(54) Title: COMPOSITIONS AND METHODS OF USE OF TARGETING PEPTIDES AGAINST PLACENTA AND ADIPOSE TISSUES

(57) Abstract: The present invention concerns compositions comprising and methods of identification and use of targeting peptides for placenta or adipose tissue. In certain embodiments, the targeting peptides comprise part or all of SHQ ID NO:5-11, SEQ ID NO:13-22 OR SHQ ID NO:144. The peptides may be attached to various therapeutic agents for targeted delivery. Adipose-targeting peptides may be used in methods for weight control, inducing weight loss and treating lipodystrophy syndrome. Adipose-targeting may also be accomplished using other binding moieties selectively targeted to adipose receptors, such as a prolactin receptor protein complex. Placenta-targeting peptides may be used to interfere with pregnancy, induce labor and/or for targeted delivery of therapeutic agents to placenta and/or fetus. In other embodiments, receptors identified by binding to placenta-targeting peptides may be used to screen compounds for potential teratogenicity. An exemplary placental receptor is FcRn/ β_2 M, and compounds that bind to FcRn/ β_2 M are potential teratogens.

COMPOSITIONS AND METHODS OF USE OF TARGETING PEPTIDES
AGAINST PLACENTA AND ADIPOSE TISSUES

BACKGROUND OF THE INVENTION

[0001] This application is a continuation in part of PCT application PCT/US01/27692, filed on September 7, 2001, the entire text of which is incorporated herein by reference. This application claims priority from U.S. Provisional Patent Application No. 60/231,266 filed September 8, 2000, and U.S. Patent Application No. 09/765,101, filed January 17, 2001. This invention was made with U.S. government support under grants grants CA90270, 1R1CA90810-01 and 1R01CA82976-01 from the National Institutes of Health. The U.S. government has certain rights in this invention.

Field of the Invention

[0002] The present invention concerns the fields of molecular medicine and targeted delivery of therapeutic agents. More specifically, the present invention relates to compositions and methods for identification and use of peptides that selectively target white adipose tissue and placenta *in vivo* or *in vitro*. In other embodiments, the invention concerns compositions and methods for screening potential teratogenic agents.

Description of Related Art

[0003] Phage display is a technique in which a phage library expresses, for example, a set of random peptide sequences of defined length, incorporated into a phage coat protein (*e.g.*, Smith and Scott, *Science* 228:1315-17, 1985; Smith and Scott, *Meth. Enzymol.* 21:228-57, 1993). Peptide sequences that bind to a target molecule, cell, tissue or organ may be identified by incubating a phage display library with the target and selecting for bound peptides (biopanning) (*e.g.*, Pasqualini and Ruoslahti, *Nature* 380:364-66, 1996; Arap *et al.*, *Science* 279:377-80, 1998a). Unbound phage may be washed away and bound phage eluted and collected. The collected phage may be amplified and taken through further binding/amplification cycles to enrich the pool of peptides for those that selectively and/or specifically bind to the target. With each cycle, the proportion of phage in the pool that contain targeting peptides for the target of

interest is enriched. After several cycles, individual phage clones may be characterized by DNA sequencing to identify the targeting peptide sequences.

[0004] Targeting peptides that exhibit selective and/or specific binding for placenta or adipose tissues have not been previously reported in the literature. Targeting peptides against placenta or adipose tissues would have a variety of potential uses. Targeting peptides against adipose tissue could be used to control obesity and related conditions. Adipose-targeting peptides would also be of potential use to treat HIV related adipose malformations such as lipodystrophia and/or hyperlipidemia (see, e.g., Zhang *et al.*, J. Clin. Endocrin. Metab. 84:4274-77, 1999; Jain *et al.*, Antiviral Res. 51:151-177, 2001; Raolin *et al.*, Prog. Lipid Res. 41:27-65, 2002). Targeting peptides against placental tissue could be used to reduce harmful effects by teragenic agents, to deliver therapeutic agents to the placenta and/or the fetus and to induce labor or spontaneous abortion. Placental receptors identified through the use of placental targeting peptides could be used to screen for potential teratogens.

[0005] Presently available methods for control of weight include dieting and surgical procedures. These often exhibit adverse effects and may not result in long-term weight loss. Dieting includes both popular (fad) diets and the use of weight loss and appetite supplements. Fad diets are only good for short-term weight loss and do not achieve long-term weight control. They are often unhealthy, since many important nutrients are missing from the diet. In addition, rapid weight loss can result in dehydration. After losing weight, the dieters typically return to their original eating habits. This often results in weight gain that can exceed the subject's weight before dieting (yo yo effect).

[0006] Appetite suppressants such as Phentermen HCl, Meridia, Xernical, Adipex-P, Bontril and Ionomin may have adverse effects, such as addiction, dry mouth, nausea, irritability, and constipation. These supplements can also lead to more serious problems like eating disorders. Weight control through use of such supplements is ineffective, with only limited weight loss achieved. Effective drugs for controlling weight, such as fenfluramine, were withdrawn from the market due to cardiotoxicity.

Surgical methods for weight reduction, such as liposuction and gastric bypass surgery, have many risks. Liposuction removes subcutaneous fat through a suction tube inserted into a small incision in the skin. Risks and complications may include scarring,

bleeding, infection, change in skin sensation, pulmonary complications, skin loss, chronic pain, etc. In gastric bypass surgery, the patient has to go through the rest of his or her life with a drastically altered stomach that can hold just two or three ounces of food. Side effects may include nausea, diarrhea, bleeding, infection, bowel blockage caused by scar tissue, hernia and adverse reactions to general anesthesia. The most serious potential risk is leakage of fluid from the stomach or intestines, which may result in abdominal infection and the need for a second surgery. None of the presently available methods for weight control is satisfactory and a need exists for improved methods of weight loss and control.

Another adipose related disease state is lipodystrophy syndrome(s) related to HIV infection (e.g., Jain *et al.*, Antiviral Res. 51:151-177, 2001). Mortality rates from HIV infection have decreased substantially following use of highly active antiretroviral therapy (HAART) (*Id.*) However, treatment with protease inhibitors as part of the HAART protocol appears to result in a number of lipid-related symptoms, such as hyperlipidemia, fat redistribution with accumulation of abdominal and cervical fat, diabetes mellitus and insulin resistance (Jain *et al.*, 2001; Yanovski *et al.*, J. Clin. Endocrin. Metab. 84:1925-1931; Raulin *et al.*, Prog. Lipid Res. 41:27-65, 2002). Although of minor significance compared to the underlying HIV infection and possible development of AIDS related complex (ARC) and/or AIDS, lipodystrophy syndrome adversely affects quality of life and may be associated with increased risk of coronary artery disease, heart attack, stroke and other adverse side effects of increased blood lipids. While treatment with metformin, an insulin-sensitizing agent, has been reported to provide some alleviation of symptoms (Hadigan *et al.*, J. Amer. Med. Assn. 284:472-477, 2000), a need exists for more effective methods of treating HIV related lipodystrophy.

[0007] Teratogens fall into two classes. The first class includes compounds that are actively or passively transferred through the materno-fetal barrier. Those target fetal development by altering cell-signaling pathways that control essential processes in the developing embryo, such as angiogenesis (D'Amato, R.J., *et al* 1994. *Proc. Natl. Acad. Sci. USA* 91: 4082-4085; Finnell, R.H.1999. *J. Allergy Clin. Immunol.* 103:337-342).

[0010] Teratogens of the second class interfere with fetal development by affecting the delivery of nutrients to the embryo through the placenta (Maranghi, F., *et al.* 1998. *Adv. Exp. Med. Biol.* 444: 129-136; Rugh, R. 1990. *The Mouse: Its Reproduction and Development*, Oxford Science Publications, Oxford). Materno-fetal molecule exchange occurs by filtration of blood from the maternal to the fetal side of the placenta through several distinct cell layers. Teratogens that target the placenta are thought to function by blocking receptors required for transport of nutrients to the fetus (Beckman, D.A., *et al.* 1990. *Teratology* 41: 395-404). Present methods of treatment primarily involve avoiding exposure of the pregnant woman to teratogens. Such methods are ineffective where the mother is unaware of her pregnancy, or for novel teratogens whose effect on fetal development have not yet been characterized. Because teratogens are identified by *in vivo* animal testing, differences in placental receptors between humans and test animals, such as mice, may result in the failure to identify teratogenic effects until multiple birth defects are reported, such as in the thalidomide tragedy. A need exists for methods of identifying the placental receptors for teratogens, in order to allow more accurate teratogen screening procedures.

SUMMARY OF THE INVENTION

[0011] The present invention solves a long-standing need in the art by providing compositions and methods of preparation and use of targeting peptides that are selective and/or specific for white adipose tissue or placenta. In some embodiments, the invention concerns particular targeting peptides selective or specific for adipose or placental tissue, including but not limited to SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144. Other embodiments concern such targeting peptides attached to therapeutic agents. In other embodiments, placental, adipose or other targeting peptides may be used to selectively or specifically deliver therapeutic agents to target tissues, such as white adipose tissue, placenta or fetal tissue. In certain embodiments, the subject methods concern the preparation and identification of targeting peptides selective or specific for a given target cell, tissue or organ, such as adipose or placenta.

[0012] One embodiment of the invention concerns isolated peptides of 100 amino acids or less in size, comprising at least 3 contiguous amino acids of a targeting peptide sequence, selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID

NO:144. In a preferred embodiment, the isolated peptide is 50 amino acids or less, more preferably 30 amino acids or less, more preferably 20 amino acids or less, more preferably 10 amino acids or less, or even more preferably 5 amino acids or less in size. In other preferred embodiments, the isolated peptide may comprise at least 4, 5, 6, 7, 8 or 9 contiguous amino acids of a targeting peptide sequence, selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144.

[0013] In certain embodiments, the isolated peptide may be attached to a molecule. In preferred embodiments, the attachment is a covalent attachment. In various embodiments, the molecule is a drug, a chemotherapeutic agent, a radioisotope, a pro-apoptosis agent, an anti-angiogenic agent, a hormone, a cytokine, a growth factor, a cytotoxic agent, a peptide, a protein, an antibiotic, an antibody, a Fab fragment of an antibody, a survival factor, an anti-apoptotic factor, a hormone antagonist, an imaging agent, a nucleic acid or an antigen. Those molecules are representative only and virtually any molecule may be attached to a targeting peptide and/or administered to a subject within the scope of the invention. In preferred embodiments, the pro-apoptosis agent is gramicidin, magainin, mellitin, defensin, cecropin, (KLAKLAK)₂ (SEQ ID NO:1), (KLAKKLA)₂ (SEQ ID NO:2), (KAAKAA)₂ (SEQ ID NO:3) or (KLKKLG)₃ (SEQ ID NO:4). In other preferred embodiments, the anti-angiogenic agent is angiostatin, pigment epithelium-derived factor, angiotensin, laminin peptides, fibronectin peptides, plasminogen activator inhibitors, tissue metalloproteinase inhibitors, interferons, interleukin 12, platelet factor 4, IP-10, Gro-β, thrombospondin, 2-methoxyestradiol, proliferin-related protein, carboxyamidotriazole, CM101, Marimastat, pentosan polysulphate, angiopoietin 2 (Regeneron), interferon-α, herbimycin A, PNU145156E, 16K prolactin fragment, Linomide, thalidomide, pentoxifylline, genistein, TNP-470, endostatin, paclitaxel, docetaxel, polyamines, a proteasome inhibitor, a kinase inhibitor, a signaling inhibitor (SU5416, SU6668, Sugen, South San Francisco, CA), accutin, cidofovir, vincristine, bleomycin, AGM-1470, platelet factor 4 or minocycline. In further preferred embodiments, the cytokine is interleukin 1 (IL-1), IL-2, IL-5, IL-10, IL-11, IL-12, IL-18, interferon-γ (IF-γ), IF-α, IF-β, tumor necrosis factor-α (TNF-α), or GM-CSF (granulocyte macrophage colony stimulating factor). Such examples are representative only and are not intended to exclude other pro-apoptosis agents, anti-angiogenic agents or cytokines known in the art.

[0014] In various embodiments, targeting peptides attached to one or more therapeutic agents may be administered to a subject, such as an animal, mammal, cat, dog, cow, pig, horse, sheep or human subject. Such administration may be of use for the treatment of various disease states. In certain embodiments, adipose-targeting peptides attached to a cytotoxic, pro-apoptotic, anti-angiogenic or other therapeutic agent may be of use in methods to treat obesity, induce weight loss and/or to treat highly active antiretroviral therapy (HAART) associated lipodystrophy syndrome. In other embodiments, placenta-targeting peptides attached to such agents may be used, for example, to induce labor or to terminate pregnancy.

[0015] In other embodiments of the invention, the isolated peptide may be attached to a macromolecular complex. In preferred embodiments, the macromolecular complex is a virus, a bacteriophage, a bacterium, a liposome, a microparticle, a magnetic bead, a yeast cell, a mammalian cell, a cell or a microdevice. These are representative examples only and macromolecular complexes within the scope of the present invention may include virtually any complex that may be attached to a targeting peptide and administered to a subject. In other preferred embodiments, the isolated peptide may be attached to a eukaryotic expression vector, more preferably a gene therapy vector.

[0016] In another embodiment, the isolated peptide may be attached to a solid support, preferably magnetic beads, Sepharose beads, agarose beads, a nitrocellulose membrane, a nylon membrane, a column chromatography matrix, a high performance liquid chromatography (HPLC) matrix or a fast performance liquid chromatography (FPLC) matrix.

[0017] Additional embodiments of the present invention concern fusion proteins comprising at least 3 contiguous amino acids of a sequence selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144. In some embodiments, larger contiguous sequences, up to a full-length sequence selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144 may be used.

[0018] Certain other embodiments concern compositions comprising the claimed isolated peptides or fusion proteins in a pharmaceutically acceptable carrier. Further embodiments concern kits comprising the claimed isolated peptides or fusion proteins in one or more containers.

[0019] Other embodiments concern methods of targeted delivery comprising selecting a targeting peptide for a desired organ, tissue or cell type, attaching said targeting peptide to a molecule, macromolecular complex or gene therapy vector, and providing said peptide attached to said molecule, complex or vector to a subject. Preferably, the targeting peptide is selected to include at least 3 contiguous amino acids from any of selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144. In certain preferred embodiments, the organ, tissue or cell type is white adipose or placenta. In other preferred embodiments, the molecule attached to the targeting peptide is a chemotherapeutic agent, an antigen or an imaging agent.

[0020] Other embodiments of the present invention concern isolated nucleic acids of 300 nucleotides or less in size, encoding a targeting peptide. In preferred embodiments, the isolated nucleic acid is 250, 225, 200, 175, 150, 125, 100, 75, 50, 40, 30, 20 or even 10 nucleotides or less in size. In other preferred embodiments, the isolated nucleic acid is incorporated into a eukaryotic or a prokaryotic expression vector. In even more preferred embodiments, the vector is a plasmid, a cosmid, a yeast artificial chromosome (YAC), a bacterial artificial chromosome (BAC), a virus or a bacteriophage. In other preferred embodiments, the isolated nucleic acid is operatively linked to a leader sequence that localizes the expressed peptide to the extracellular surface of a host cell.

[0021] Additional embodiments of the present invention concern methods of treating a disease state comprising selecting a targeting peptide that targets cells associated with the disease state, attaching one or more molecules effective to treat the disease state to the peptide, and administering the peptide to a subject with the disease state. Preferably, the targeting peptide includes at least three contiguous amino acids selected from any of selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144. In preferred embodiments the disease state is obesity, lipodystrophy or a related condition.

[0022] In certain embodiments, the methods concern Biopanning and Rapid Analysis of Selective Interactive Ligands (BRASIL), a novel method for phage display that results in decreased background of non-specific phage binding, while retaining selective binding of phage to cell receptors. In preferred embodiments, targeting peptides are identified by exposing a subject to a phage display library, collecting samples of one or more organs, tissues or cell types, separating the samples into isolated cells or small clumps of cells

suspended in an aqueous phase, layering the aqueous phase over an organic phase, centrifuging the two phases so that the cells are pelleted at the bottom of a centrifuge tube and collecting phage from the pellet. In an even more preferred embodiment, the organic phase is dibutylphthalate.

[0023] In other embodiments, phage that bind to a target organ, tissue or cell type, for example to adipose tissue or placenta, may be pre-screened or post-screened against a subject lacking that organ, tissue or cell type. Phage that bind to the subject lacking the target organ, tissue or cell type are removed from the library prior to screening in subjects possessing the organ, tissue or cell type.

[0024] In preferred embodiments, targeting phage may be recovered from specific cell types or sub-types present in an organ or tissue after selection of the cell type by PALM (Positioning and Ablation with Laser Microbeams). PALM allows specific cell types to be selected from, for example, a thin section of an organ or tissue. Phage may be recovered from the selected sample.

[0025] In another embodiment, a phage display library displaying the antigen binding portions of antibodies from a subject is prepared, the library is screened against one or more antigens and phage that bind to the antigens are collected. In more preferred embodiments, the antigen is a targeting peptide.

[0026] In certain embodiments, the methods and compositions may be used to identify one or more receptors for a targeting peptide. In alternative embodiments, the compositions and methods may be used to identify naturally occurring ligands for known or newly identified receptors. In preferred embodiments, the receptor may be a placental receptor for teratogens. In some embodiments, the placental teratogen receptor(s) identified may be used for screening of potential teratogens for receptor binding.

[0027] In some embodiments, the methods may comprise contacting a targeting peptide to an organ, tissue or cell containing a receptor of interest, allowing the peptide to bind to the receptor, and identifying the receptor by its binding to the peptide. In preferred embodiments, the targeting peptide contains at least three contiguous amino acids selected from any of selected from any of SEQ ID NO:5-11, SEQ ID NO:13-22 and SEQ ID NO:144. In other preferred embodiments, the targeting peptide may comprise a portion of an antibody against the receptor.

[0028] In alternative embodiments, the targeting peptide may contain a random amino acid sequence. The skilled artisan will realize that the contacting step can utilize intact organs, tissues or cells, or may alternatively utilize homogenates or detergent extracts of the organs, tissues or cells. In certain embodiments, the cells to be contacted may be genetically engineered to express a suspected receptor for the targeting peptide. In a preferred embodiment, the targeting peptide is modified with a reactive moiety that allows its covalent attachment to the receptor. In a more preferred embodiment, the reactive moiety is a photoreactive group that becomes covalently attached to the receptor when activated by light. In another preferred embodiment, the peptide is attached to a solid support and the receptor is purified by affinity chromatography. In other preferred embodiments, the solid support comprises magnetic beads, Sepharose beads, agarose beads, a nitrocellulose membrane, a nylon membrane, a column chromatography matrix, a high performance liquid chromatography (HPLC) matrix or a fast performance liquid chromatography (FPLC) matrix.

[0029] In certain embodiments, the targeting peptide may inhibit the activity of a receptor upon binding to the receptor. The skilled artisan will realize that receptor activity can be assayed by a variety of methods known in the art, including but not limited to catalytic activity and binding activity. In other embodiments, binding of a targeting peptide to a receptor may inhibit a transport activity of the receptor.

[0030] In alternative embodiments, one or more ligands for a receptor of interest may be identified by the disclosed methods and compositions. One or more targeting peptides that mimic part or all of a naturally occurring ligand may be identified by phage display and biopanning *in vivo* or *in vitro*. A naturally occurring ligand may be identified by homology with a single targeting peptide that binds to the receptor, or a consensus motif of sequences that bind to the receptor. In other alternative embodiments, an antibody may be prepared against one or more targeting peptides that bind to a receptor of interest. Such antibodies may be used for identification or immunoaffinity purification of the native ligand.

[0031] In certain embodiments, the targeting peptides of the present invention are of use for the selective delivery of therapeutic agents, including but not limited to gene therapy vectors and fusion proteins, to specific organs, tissues or cell types. The skilled

artisan will realize that the scope of the claimed methods of use include any disease state that can be treated by targeted delivery of a therapeutic agent to a desired organ, tissue or cell type. Although such disease states include those where the diseased cells are confined to a specific organ, tissue or cell type, other disease states may be treated by an organ, tissue or cell type-targeting approach. In particular embodiments, the organ, tissue or cell type may comprise white adipose tissue or placenta.

[0032] Certain embodiments concern methods of obtaining antibodies against an antigen. In preferred embodiments, the antigen comprises one or more targeting peptides. The targeting peptides are prepared and immobilized on a solid support, serum-containing antibodies is added and antibodies that bind to the targeting peptides are collected.

BRIEF DESCRIPTION OF THE DRAWINGS

[0033] The following drawings form part of the present specification and are included to further demonstrate certain aspects of the present invention. The invention may be better understood by reference to one or more of these drawings in combination with the detailed description of specific embodiments presented herein.

[0034] **FIG. 1.** Validation of placenta homing phage. Phage bearing targeting peptides were injected into pregnant mice and their recovery from placenta was compared to control fd-tet phage without targeting sequences. The placenta homing phage clones were: PA - TPKTSVT (SEQ ID NO:5), PC - RAPGGVR (SEQ ID NO:7), PE - LGLRSVG (SEQ ID NO:10), PF - YIRPFIL (SEQ ID NO:9).

[0035] **FIG. 2.** Validation of adipose homing peptides. Phage bearing targeting peptides were injected into obese mice and their recovery from adipose tissue was compared to control fd-tet phage without targeting sequences.

FIG. 3. *In vivo* homing of the TPKTSVT (SEQ ID NO:5) motif to the mouse villous yolk sac (vys). (A) and (B) anti-phage immunohistochemistry; (C) and (D) anti-GST immunohistochemistry; (E) and (F) FITC immunofluorescence in paraffin sections of placentas from 18 dpc (days post-conception) pregnant mice injected intravenously 6 h prior to tissue processing with: (A) control insertless phage, (B) TPKTSVT (SEQ ID NO:5) phage, (C) control GST peptide, (D) TPKTSVT (SEQ ID NO:5) linked to GST

peptide, (E) control FITC-peptide, or (F) TPKTSVT (SEQ ID NO:5) linked to FITC peptide. Homing of the TPKTSVT (SEQ ID NO:5) peptide to the vvs (dark arrows, D) and translocation to the embryonic capillaries (light arrow, D) are indicated. Only the vvs is shown in (C-F). Bar:100 μ m (A-B); 20 μ m (C-F).

FIG. 4. The TPKTSVT (SEQ ID NO:5) peptide specifically binds a placental transporter. (A) Recovery of indicated phage from embryos carried by 18 dpc pregnant mice intravenously injected (tail vein) with 10^{10} TU of the indicated phage 6 h prior to phage recovery or immunohistochemistry. Control phage (light cross-hatch) showed no selective targeting of placenta. TPKTSVT (SEQ ID NO:5) phage were administered alone (dark cross-hatched) or co-administered with control-GST (black) or TPKTSVT (SEQ ID NO:5) linked to GST (white bar). Shown are mean \pm SEM (standard error) from different embryos. (B-D) Anti-phage HRP immunohistochemistry (arrowheads) in paraffin sections of the vvs from the corresponding mice, as indicated. Asterisks mark embryonic capillaries. Bar:20 μ m.

FIG. 5. The TPKTSVT (SEQ ID NO:5) peptide blocks placental IgG transcytosis. A 18 dpc pregnant mouse was intravenously injected with: (A) 100 mg of control GST fusion or (B) TPKTSVT (SEQ ID NO:5) linked to GST. The IgG distribution in the placenta after 6 h of peptide circulation was detected by anti-mouse IgG immunohistochemistry in paraffin sections. Strong immunostaining is noted in the vvs of mice injected with a control GST fusion (arrowheads) and in the labyrinth of wild-type mice injected with either TPKTSVT (SEQ ID NO:5) linked to GST or control GST fusion (asterisks), but not in the vvs of TPKTSVT (SEQ ID NO:5) linked to GST fusion. Bar: 100 μ m. (C) and (D) A hypothetical model for the TPKTSVT (SEQ ID NO:5) peptide function. (C) Normally, the FcRn/ β_2 m complex transports IgG from maternal circulation through the labyrinth layer and then the yolk sac placenta (vvs) and into the embryo. (D) Targeting of the FcRn/ β_2 m with TPKTSVT (SEQ ID NO:5) peptide can block the receptor complex and the transport of IgG or phage into the embryo.

FIG 6. Placental targeting by the TPKTSVT (SEQ ID NO:5) peptide requires a functional FcRn/ β_2 m receptor complex. (A) Relative phage recovery (placenta TU/ml to blood TU/ml ratio) from placentas derived from 18 dpc pregnant wild-type or β_2 m-deficient mice injected with 10^{10} TU of control insertless phage (black) or TPKTSVT

(SEQ ID NO:5) phage (white) 6 h prior to phage recovery or immunohistochemistry. Shown are mean \pm SEM from individual placentas. (B) and (C) Anti-phage immunohistochemistry in paraffin sections of the placenta from 18 dpc pregnant β_2 -null mice intravenously injected with (B) TPKTSVT (SEQ ID NO:5) phage or (C) control placenta-homing phage displaying the YIRPFIL (SEQ ID NO:9) peptide 6 h prior to tissue processing. Staining of a placenta-homing phage displaying the unrelated peptide YIRPFIL (SEQ ID NO:9) is detected in the labyrinth blood vessels (arrowheads). Bar:100 μ m.

FIG. 7. TPKTSVT (SEQ ID NO:5) peptide inhibits mouse pregnancy and is teratogenic. (A) Pregnancy courses (representative from 5 independent experiments) in mice subcutaneously injected with the indicated phage or peptides were monitored by daily weighing of the mice upon each injection (arrows). (B) Appearance of a normally developed 20 dpc embryo (left) for control GST fusion treatment compared to a representative 20 dpc embryo (right) resulting from TPKTSVT (SEQ ID NO:5) linked to GST fusion treatment. A severely teratogenic phenotype is observed with the placental targeting fusion peptide. (C) and (D) Hematoxylin/eosin staining of 20 dpc paraffin-embedded placentas derived from mice injected for 7 days with (C) control GST fusion or (D) the TPKTSVT (SEQ ID NO:5) linked to GST fusion peptide. Note hemorrhage (black asterisks), necrosis (white asterisks), and fibrosis (arrowheads). Bar:500 μ m (50 μ m for insets).

FIG. 8. *In vivo* fat homing of the CKGGRKDC (SEQ ID NO:22) motif in genetically obese mice. (A) and (B) Anti-phage immunohistochemistry in paraffin sections of subcutaneous white fat from leptin-deficient mice intravenously injected 6 hr prior to tissue processing. (C) and (D) Peptide-FITC immunofluorescence in paraffin sections of subcutaneous white fat from leptin-deficient mice intravenously injected 6 hr prior to tissue processing. Mice were injected with (A) CKGGRKDC (SEQ ID NO:22) phage, (B) control insertless phage, (C) CKGGRKDC (SEQ ID NO:22) linked to FITC peptide, or (D) control CARAC (SEQ ID NO:12) linked to FITC peptide. Homing of the CKGGRKDC (SEQ ID NO:22) peptide to fat blood vessels (arrows) and its uptake by fat endothelium are indicated. Bar: 10 μ m.

[0036] FIG. 9. *In vivo* fat homing of the CKGGRKDC (SEQ ID NO:22) motif in wild-type mice. (A), (C) and (E) Peptide-FITC immunofluorescence or (B), (D) and (F) lectin-rhodamine immunofluorescence in blood vessels of (A), (B), (E) and (F) subcutaneous white fat or (C) and (D) pancreas controls detected in paraffin-sectioned tissues from c57bl/6 mice intravenously co-injected 5 min prior to tissue processing. Mice were injected with (A), (B), (C) and (D) CKGGRKDC (SEQ ID NO:22) linked to FITC peptide and lectin-rhodamine; or (E) and (F) control CARAC (SEQ ID NO:12) linked to FITC peptide and lectin-rhodamine. (B), (D) and (F) Arrows show endothelium marked with lectin. (A) Arrows show homing of the CKGGRKDC (SEQ ID NO:22) peptide to fat endothelium. Bar: 10 μ m.

FIG. 10. Treatment of mouse obesity with fat vasculature-targeted apoptosis. Three cohorts (n=3) of (A) high-fat cafeteria diet-fed obese c57bl/6 mice; or (B) regular diet-fed old (~1year) c57bl/6 mice were each subcutaneously injected daily with equimolar amounts of the indicated peptides. Mouse body mass measurement was taken on days when injections were performed (injections were skipped on days for which body mass measurement is not shown). Error bars are SEM for the measurements in three mice.

[0037] FIG. 11. Fat resorption induced by fat vasculature-targeted apoptosis. (A) Representative high-fat cafeteria diet-fed obese c57bl/6 mice; (B) and (C) representative regular diet-fed old (~1year) c57bl/6 mice; or (D) epididymal fat from representative regular diet-fed old c57bl/6 mice from the experiment described in FIG. 10. Whole mice (A), subcutaneous fat (B), peritoneal fat (C) and total epididymal fat (D) from the corresponding indicated treatments were photographed 1 week (A) or 3 weeks (B), (C) and (D) after the beginning of subcutaneous injections. The injected peptides were CKGGRKDC (SEQ ID NO:22) linked to (KLAKLAK)₂ (SEQ ID NO:1) (left column), CARAC (SEQ ID NO:12) linked to (KLAKLAK)₂ (SEQ ID NO:1) (middle column), and CKGGRKDC (SEQ ID NO:22) co-administered with (KLAKLAK)₂ (SEQ ID NO:1) (right column).

[0038] FIG. 12. Destruction of fat blood vessels as a result of targeted apoptosis. (A) Tunnel immunohistochemistry, (B) secondary antibody only negative tunnel staining control and (C) and (D) hematoxylin/eosin staining of white fat of mice. (A), (B) and (C)

Mice were treated with CKGGRAKDC (SEQ ID NO:22) linked to (KLAKLAK)₂ (SEQ ID NO:1). (D) Mice were treated with CARAC (SEQ ID NO:12) linked to (KLAKLAK)₂ (SEQ ID NO:1). Apoptosis (arrows, (A)) and necrosis/lymphocyte infiltration (arrows, (C)) in response to CKGGRAKDC (SEQ ID NO:22) linked to (KLAKLAK)₂ (SEQ ID NO:1) treatment are indicated. Bar: 10 μ m.

[0039] FIG. 13. Spleen targeting *in vitro* using BRASIL. Binding of Fab clones #2, #6, #10, #12 and control Fab clone NPC-3TT were directly compared to each other.

[0040] FIG. 14. Spleen targeting *in vivo* using BRASIL. Binding of Fab clones #2, #6, #10 and #12 to spleen tissue was compared to binding of Fab control clone NPC-3TT.

[0041] FIG. 15. Spleen targeting *in vivo* using BRASIL. Binding of Fab clones #2, #6, #10, #12 was compared to binding of Fd-tet phage.

[0042] FIG. 16. Spleen targeting *in vivo* using BRASIL. Binding of Fab clone #10 to spleen tissue was compared to binding of Fab control clone NPC-3TT and Fd-tet phage.

[0043] FIG. 17. Binding of Fab clone #10 to spleen *versus* bone marrow in comparison to Fd-tet phage.

FIG. 18. Binding of B3 cytoplasmic domain-selected phage to immobilized proteins. GST fusion proteins or GST alone were coated on microtiter wells at 10 μ g/ml and used to bind phage-expressing endostatin targeting peptides. Each phage is identified by the peptide sequence it displayed: GLDTYRGSP (SEQ ID NO:30); YDWWYPWSW (SEQ ID NO:29); CLRQSYSYNC (SEQ ID NO:38); SDNRYIGSW (SEQ ID NO:31); CEQRQTQEGC (SEQ ID NO:27); CFQNRNRC (SEQ ID NO:36). The data represent the mean colony counts from triplicate wells, with standard error of less than 10% of the mean.

[0044] FIG. 19. Binding of B5 cytoplasmic domain-selected phage to immobilized proteins. GST fusion proteins or GST alone were coated on microtiter wells at 10 μ g/ml and used to bind phage-expressing endostatin binding peptides. Each phage is identified by the peptide sequence it displayed: (A) DEEGYYMMR (SEQ ID NO:44); (B) KQFSYRYLL (SEQ ID NO:45); (C) CEPYWDGWFC (SEQ ID NO:40); (D)

VVISYSMPD (SEQ ID NO:46); and (E) CYIWPDSGLC (SEQ ID NO:39). The data represent the mean colony counts from triplicate wells, with standard error less than 10% of the mean.

[0045] **FIG. 20.** Binding of the cytoplasmic-domain binding phage to B3 immobilized protein and inhibition with the synthetic peptide. Phage were incubated on wells coated with GST-B3cyto in the presence of increasing concentrations of the corresponding synthetic peptide or a control peptide. The data represent the mean colony counts from triplicate wells, with standard error less than 10% of the mean.

[0046] **FIG. 21.** Binding of the cytoplasmic-domain binding phage to B5 immobilized protein and inhibition with the synthetic peptide. Phage were incubated on wells coated with GST-B5cyto in the presence of increasing concentrations of the corresponding synthetic peptide or a control peptide. The data represent the mean colony counts from triplicate wells, with standard error less than 10% of the mean.

[0047] **FIG. 22.** Binding of phage to immobilized B3-GST and B5-GST after phosphorylation. Phage were phosphorylated with Fyn kinase. Insertless phage were used as a control. Phage were incubated on wells coated with GST-B3cyto or GST-B5cyto. The data represent the mean colony counts from triplicate wells, with standard error less than 10% of the mean.

[0048] **FIG. 23.** Binding of phage to immobilized GST fusion proteins after phosphorylation. Phages were phosphorylated with Fyn kinase. Insertless phage was used as a control. Phage were incubated on wells coated with GST-cytoplasmic domains. The data represent the mean of colony counts from triplicate wells, with standard error less than 10% of the mean.

[0049] **FIG. 24.** Effect of integrin cytoplasmic domain binding peptides on cell proliferation. Serum-deprived cells were cultured for 24 h. and the proliferation was determined by [^3H] thymidine (1 $\mu\text{Ci}/\text{ml}$) uptake measurements. In a positive control, VEGF was added back to serum-starved cells. Each experiment was performed three times with triplicates, and the results were expressed as the mean \pm SD.

[0050] **FIG. 25.** Effect of penetratin peptide chimeras on endothelial cell migration. Cell migration assay were performed in a 48-well microchemotaxis chamber. Five

random high-power fields (magnitude 40 \times) were counted in each well. The results show that both β 3-integrin cytoplasmic domain-binding peptides (Y-18 and TYR-11) increase cell migration while penetratin does not affect the cells.

[0051] FIG. 26. Penetratin peptide chimera binding to the β 5 cytoplasmic domain induces programmed cell death. 10⁶ HUVEC cells were harvested in complete media and 15 μ M penetratin peptide chimeras were added to the cells. After four, eight and twelve hours the cells were stained with Propidium Iodide (PI) and induction of apoptosis was analyzed by cytometric analysis. (a) Profile obtained with starved cells after 24 h. (b) Confluent cells in complete media. (c) 15 μ M of penetratin after four hours. (d) 15 μ M of VISY-penetratin chimera after four hours. Cells analyzed after eight and twelve hours showed similar profiles for the percentage of G₀/G₁.

[0052] FIG. 27. Specificity of the antibodies raised against β 3- or β 5-selected phage (ELISA). Increasing dilutions of sera obtained after three immunizations with GLDTYRGSP (SEQ ID NO:30) or SDNRYIGSW (SEQ ID NO:31) conjugated to KLH were incubated on microtiter wells coated with 10 μ g of SDNRYIGSW (SEQ ID NO:31, Y-18), GLDTYRGSP (SEQ ID NO:30, TYR-11) or control peptides. Preimmune sera were used as controls. After incubation with HRP-goat anti-rabbit, OD was measured at 405 nm. The data represent the means from triplicate wells, with standard error less than 10%.

[0053] FIG. 28. Specificity of the antibodies raised against β 3- or β 5-selected phage (ELISA). Sera obtained after three immunizations with SDNRYIGSW (SEQ ID NO:31, Y-18) or GLDTYRGSP (SEQ ID NO:30, TYR-11) conjugated to KLH were incubated in microtiter wells coated with 10 μ g of TYR-11 or Y-18. GLDTYRGSP (SEQ ID NO:30) or SDNRYIGSW (SEQ ID NO:31) and control peptides were added in solution. After incubation with HRP goat anti-rabbit, OD was measured at 405 nm. The data represent the means from triplicate wells, with standard error less than 10%. Peptides added in solution specifically block the reactivity with the immobilized peptides.

[0054] FIG. 29A. Competitive binding of Annexin V to β 5 integrin with VISY peptide. Binding assays were performed by ELISA.

[0055] FIG. 29B. Relative levels of binding of anti-Annexin V antibody to purified Annexin V protein and VISY peptide.

[0056] FIG. 30. Chimeric peptide containing VISY peptide linked to penetratin (antennapedia) induces apoptosis. VISY induced apoptosis was inhibited by addition of a caspase inhibitor (zVAD).

[0057] FIG. 31. APA-binding phage specifically bind tumors. Equal amounts of phage were injected into the tail veins of mice bearing MDA-MB-435-derived tumors and phage were recovered after perfusion. Mean values for phage recovered from the tumor or control tissue (brain) and the standard error from triplicate platings are shown.

[0058] FIG. 32. CPRECESIC (SEQ ID NO:56) is a specific inhibitor of APA activity. APA enzyme activity was assayed in the presence of increasing concentrations of either GACVRLSACGA (SEQ ID NO:57) (control) or CPRECESIC (SEQ ID NO:56) peptide. The IC_{50} for APA inhibition by CPRECESIC (SEQ ID NO:56) was estimated at 800 μ M. Error bars are the standard error of the means of triplicate wells. The experiment was repeated three times with similar results.

[0059] FIG. 33. CPRECESIC (SEQ ID NO:56) inhibits HUVEC migration. HUVECs were stimulated with VEGF-A (10 ng/ml). The assay was performed in a Boyden microchemotaxis chamber, and cells were allowed to migrate through an 8- μ m pore filter for 5 h at 37°C. GACVRLSACGA (SEQ ID NO:57) (control) and CPRECESIC (SEQ ID NO:56) peptides were tested at 1 mM concentration. Migrated cells were stained and five high-power fields (magnitude 100 \times) for each microwell were counted. Error bars are the standard error of the means of triplicate microwells.

[0060] FIG. 34. CPRECESIC (SEQ ID NO:56) inhibits HUVEC proliferation. Cells were stimulated with VEGF-A (10 ng/ml), and growth was evaluated at the indicated times by a colorimetric assay based on crystal violet staining. Error bars are the standard error of the means of triplicate wells. Each experiment was repeated at least twice with similar results.

[0061] FIG. 35. Protocol for *in vivo* biopanning for phage targeted in mouse pancreas, kidneys, liver, lungs and adrenal gland.

[0062] FIG. 36. Protocol for recovery of phage by infection of *E. coli* or recovery of phage DNA by amplification and subcloning.

[0063] FIG. 37. Pancreatic islet targeting peptides and homologous proteins. Candidate endogenous proteins mimicked by the pancreatic islet targeting peptides CVSNPRWK (SEQ ID NO:131), CVPRRWDC (SEQ ID NO:128), CQHTSGRC (SEQ ID NO:129) and CRARGWLLC (SEQ ID NO:130), identified by standard homology searches.

[0064] FIG. 38. Pancreatic islet targeting peptides and homologous proteins. Candidate endogenous proteins mimicked by the pancreatic islet targeting peptides CGGVHALRC (SEQ ID NO:98), CFNRTWIGC (SEQ ID NO:132) and CWSRQGGC (SEQ ID NO:134, identified by standard homology searches.

[0065] FIG. 39. Pancreatic islet targeting peptides and homologous proteins. Candidate endogenous proteins mimicked by the pancreatic islet targeting peptides CLASGMDAC (SEQ ID NO:138), CHDERTGRC (SEQ ID NO:139), CAHHALMEC (SEQ ID NO:140) and CMQGARTSC (SEQ ID NO:142), identified by standard homology searches.

[0066] FIG. 40. Pancreatic islet targeting peptides and homologous proteins. Candidate endogenous proteins mimicked by the pancreatic islet targeting peptides CHVLWSTRC (SEQ ID NO:135), CMSSPGVAC (SEQ ID NO:137) and CLGLLMAGC (SEQ ID NO:136), identified by standard homology searches.

DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

[0067] As used herein in the specification, "a" or "an" may mean one or more. As used herein in the claim(s), in conjunction with the word "comprising," the words "a" or "an" may mean one or more than one. As used herein "another" may mean at least a second or more of an item.

[0068] A "targeting peptide" is a peptide comprising a contiguous sequence of amino acids, which is characterized by selective localization to an organ, tissue or cell type. Selective localization may be determined, for example, by methods disclosed below, wherein the putative targeting peptide sequence is incorporated into a protein that is displayed on the outer surface of a phage. Administration to a subject of a library of

such phage that have been genetically engineered to express a multitude of such targeting peptides of different amino acid sequence is followed by collection of one or more organs, tissues or cell types from the subject and identification of phage found in that organ, tissue or cell type. A phage expressing a targeting peptide sequence is considered to be selectively localized to a tissue or organ if it exhibits greater binding in that tissue or organ compared to a control tissue or organ. Preferably, selective localization of a targeting peptide should result in a two-fold or higher enrichment of the phage in the target organ, tissue or cell type, compared to a control organ, tissue or cell type. Selective localization resulting in at least a three-fold, four-fold, five-fold, six-fold, seven-fold, eight-fold, nine-fold, ten-fold or higher enrichment in the target organ compared to a control organ, tissue or cell type is more preferred. Alternatively, a phage expressing a targeting peptide sequence that exhibits selective localization preferably shows an increased enrichment in the target organ compared to a control organ when phage recovered from the target organ are reinjected into a second host for another round of screening. Further enrichment may be exhibited following a third round of screening. Another alternative means to determine selective localization is that phage expressing the putative target peptide preferably exhibit a two-fold, more preferably a three-fold or higher enrichment in the target organ compared to control phage that express a non-specific peptide or that have not been genetically engineered to express any putative target peptides. Another means to determine selective localization is that localization to the target organ of phage expressing the target peptide is at least partially blocked by the co-administration of a synthetic peptide containing the target peptide sequence. "Targeting peptide" and "homings peptide" are used synonymously herein.

[0069] A "phage display library" means a collection of phage that have been genetically engineered to express a set of putative targeting peptides on their outer surface. In preferred embodiments, DNA sequences encoding the putative targeting peptides are inserted in frame into a gene encoding a phage capsule protein. In other preferred embodiments, the putative targeting peptide sequences are in part random mixtures of all twenty amino acids and in part non-random. In certain preferred embodiments the putative targeting peptides of the phage display library exhibit one or more cysteine residues at fixed locations within the targeting peptide sequence. Cysteines may be used, for example, to create a cyclic peptide.

[0070] A "macromolecular complex" refers to a collection of molecules that may be random, ordered or partially ordered in their arrangement. The term encompasses biological organisms such as bacteriophage, viruses, bacteria, unicellular pathogenic organisms, multicellular pathogenic organisms and prokaryotic or eukaryotic cells. The term also encompasses non-living assemblages of molecules, such as liposomes, microcapsules, microparticles, magnetic beads and microdevices. The only requirement is that the complex contains more than one molecule. The molecules may be identical, or may differ from each other.

[0071] A "receptor" for a targeting peptide includes but is not limited to any molecule or macromolecular complex that binds to a targeting peptide. Non-limiting examples of receptors include peptides, proteins, glycoproteins, lipoproteins, epitopes, lipids, carbohydrates, multi-molecular structures, a specific conformation of one or more molecules and a morphoanatomic entity. In preferred embodiments, a "receptor" is a naturally occurring molecule or complex of molecules that is present on the luminal surface of cells forming blood vessels within a target organ, tissue or cell type.

[0072] A "subject" refers generally to a mammal. In certain preferred embodiments, the subject is a mouse or rabbit. In even more preferred embodiments, the subject is a human.

Phage Display

[0073] Recently, an *in vivo* selection system was developed using phage display libraries to identify organ, tissue or cell type-targeting peptides in a mouse model system. Phage display libraries expressing transgenic peptides on the surface of bacteriophage were initially developed to map epitope binding sites of immunoglobulins (Smith, GP and Scott, JK, 1985. *Science*, 228:1315-1317, Smith, GP and Scott, JK, 1993. *Meth. Enzymol.* 21:228-257). Such libraries can be generated by inserting random oligonucleotides into cDNAs encoding a phage surface protein, generating collections of phage particles displaying unique peptides in as many as 10^9 permutations. (Pasqualini, R. and Ruoslahti, E, 1996, *Nature*, 380: 364-366; Arap *et al.*, 1998a; Arap *et al.*, 1998b, *Curr. Opin. Oncol.* 10:560-565).

[0074] Intravenous administration of phage display libraries to mice was followed by the recovery of phage from individual organs (Pasqualini and Ruoslahti, 1996). Phage

were recovered that were capable of selective homing to the vascular beds of different mouse organs, tissues or cell types, based on the specific targeting peptide sequences expressed on the outer surface of the phage (Pasqualini and Ruoslahti, 1996). A variety of organ and tumor-homing peptides have been identified by this method (Rajotte *et al.*, 1998, *J. Clin. Invest.* 102:430-437; Rajotte *et al.*, 1999, *J. Biol. Chem.* 274:11593-11598; Koivunen *et al.*, 1999a, *Nature Biotechnol.* 17: 768-774; Burg M, *et al.*, 1999, *Cancer Res.* 58:2869-2874; Pasqualini, 1999, *Quart. J. Nucl. Med.* 43:159-162). Each of those targeting peptides bound to different receptors that were selectively expressed on the vasculature of the mouse target tissue (Pasqualini, 1999; Pasqualini *et al.*, 2000; Folkman J. *Nature Biotechnol.* 15:510, 1997; Folkman J. *Nature Med* 1:27-31, 1995). Tumor-homing peptides bound to receptors that were upregulated in the tumor angiogenic vasculature of mice (Brooks, P.C., *et al. Cell* 79:1157-1164, 1994b; Pasqualini *et al.*, 2000). In addition to identifying individual targeting peptides selective for an organ, tissue or cell type (Pasqualini and Ruoslahti, 1996; Arap *et al.*, 1998a; Koivunen *et al.*, *Methods Mol. Biol.* 129: 3-17, 1999b), this system has been used to identify endothelial cell surface markers that are expressed in mice *in vivo* (Rajotte and Ruoslahti, 1999).

[0075] Attachment of therapeutic agents to targeting peptides resulted in the selective delivery of the agent to a desired organ, tissue or cell type in the mouse model system. Targeted delivery of chemotherapeutic agents and proapoptotic peptides to receptors located in tumor angiogenic vasculature resulted in a marked increase in therapeutic efficacy and a decrease in systemic toxicity in tumor bearing mouse models (Arap *et al.*, 1998a, 1998b; Ellerby *et al.*, *Nature Med* 9:1032-1038, 1999).

[0076] The methods described herein for identification of targeting peptides involve the *in vivo* administration of phage display libraries. Various methods of phage display and methods for producing diverse populations of peptides are well known in the art. For example, U.S. Pat. Nos. 5,223,409; 5,622,699 and 6,068,829 disclose methods for preparing a phage library. The phage display technique involves genetically manipulating bacteriophage so that small peptides can be expressed on their surface (Smith and Scott, 1985, 1993). The potential range of applications for this technique is quite broad, and the past decade has seen considerable progress in the construction of phage-displayed peptide libraries and in the development of screening methods in which

the libraries are used to isolate peptide ligands. For example, the use of peptide libraries has made it possible to characterize interacting sites and receptor-ligand binding motifs within many proteins, such as antibodies involved in inflammatory reactions or integrins that mediate cellular adherence. This method has also been used to identify novel peptide ligands that serve as leads to the development of peptidomimetic drugs or imaging agents (Arap *et al.*, 1998a). In addition to peptides, larger protein domains such as single-chain antibodies can also be displayed on the surface of phage particles (Arap *et al.*, 1998a).

[0077] Targeting peptides selective for a given organ, tissue or cell type can be isolated by "biopanning" (Pasqualini and Ruoslahti, 1996; Pasqualini, 1999). In brief, a library of phage containing putative targeting peptides is administered to an animal or human and samples of organs, tissues or cell types containing phage are collected. In preferred embodiments utilizing filamentous phage, the phage may be propagated *in vitro* between rounds of biopanning in pilus-positive bacteria. The bacteria are not lysed by the phage but rather secrete multiple copies of phage that display a particular insert. Phage that bind to a target molecule can be eluted from the target organ, tissue or cell type and then amplified by growing them in host bacteria. If desired, the amplified phage can be administered to a host and samples of organs, tissues or cell types again collected. Multiple rounds of biopanning can be performed until a population of selective binders is obtained. The amino acid sequence of the peptides is determined by sequencing the DNA corresponding to the targeting peptide insert in the phage genome. The identified targeting peptide can then be produced as a synthetic peptide by standard protein chemistry techniques (Arap *et al.*, 1998a, Smith and Scott, 1985). This approach allows circulating targeting peptides to be detected in an unbiased functional assay, without any preconceived notions about the nature of their target. Once a candidate target is identified as the receptor of a targeting peptide, it can be isolated, purified and cloned by using standard biochemical methods (Pasqualini, 1999; Rajotte and Ruoslahti, 1999).

[0078] In certain embodiments, a subtraction protocol is used with to further reduce background phage binding. The purpose of subtraction is to remove phage from the library that bind to cells other than the cell of interest, or that bind to inactivated cells. In

alternative embodiments, the phage library may be prescreened against a subject who does not possess the targeted cell, tissue or organ. For example, placenta-binding peptides may be identified after prescreening a library against a male or non-pregnant female subject. After subtraction the library may be screened against the cell, tissue or organ of interest. In another alternative embodiment, an unstimulated, quiescent cell type, tissue or organ may be screened against the library and binding phage removed. The cell line, tissue or organ is then activated, for example by administration of a hormone, growth factor, cytokine or chemokine and the activated cell type, tissue or organ screened against the subtracted phage library.

[0079] Other methods of subtraction protocols are known and may be used in the practice of the present invention, for example as disclosed in U.S. Patent Nos. 5,840,841, 5,705,610, 5,670,312 and 5,492,807.

Choice of phage display system.

[0080] Previous *in vivo* selection studies performed in mice preferentially employed libraries of random peptides expressed as fusion proteins with the gene III capsular protein in the FUSE5 vector (Pasqualini and Ruoslahti, 1996). The number and diversity of individual clones present in a given library is a significant factor for the success of *in vivo* selection. It is preferred to use primary libraries, which are less likely to have an over-representation of defective phage clones (Koivunen *et al.*, 1999b). The preparation of a library should be optimized to between 10^8 - 10^9 transducing units (T.U.)/ml. In certain embodiments, a bulk amplification strategy is applied between each round of selection.

[0081] Phage libraries displaying linear, cyclic, or double cyclic peptides may be used within the scope of the present invention. However, phage libraries displaying 3 to 10 random residues in a cyclic insert (CX₃₋₁₀C) are preferred, since single cyclic peptides tend to have a higher affinity for the target organ than linear peptides. Libraries displaying double-cyclic peptides (such as CX₃C X₃CX₃C; Rojotte *et al.*, 1998) have been successfully used. However, the production of the cognate synthetic peptides, although possible, can be complex due to the multiple conformers with different disulfide bridge arrangements.

Identification of homing peptides and receptors by in vivo phage display in mice.

[0082] *In vivo* selection of peptides from phage-display peptide libraries administered to mice has been used to identify targeting peptides selective for normal mouse brain, kidney, lung, skin, pancreas, retina, intestine, uterus, prostate, and adrenal gland (Pasqualini and Ruoslahti, 1996; Pasqualini, 1999; Rajotte *et al.*, 1998). These results show that the vascular endothelium of normal organs is sufficiently heterogeneous to allow differential targeting with peptide probes (Pasqualini and Ruoslahti, 1996; Rajotte *et al.*, 1998). A means of identifying peptides that home to the angiogenic vasculature of tumors has been devised, as described below. A panel of peptide motifs that target the blood vessels of tumor xenografts in nude mice has been assembled (Arap *et al.*, 1998a; reviewed in Pasqualini, 1999). These motifs include the sequences RGD-4C, NGR, and GSL. The RGD-4C peptide has previously been identified as selectively binding α_v integrins and has been shown to home to the vasculature of tumor xenografts in nude mice (Arap *et al.*, 1998a, 1998b; Pasqualini *et al.*, *Nature Biotechnol* 15: 542-546, 1997).

[0083] The receptors for the tumor homing RGD4C targeting peptide has been identified as α_v integrins (Pasqualini *et al.*, 1997). The α_v integrins play an important role in angiogenesis. The $\alpha_v\beta_3$ and $\alpha_v\beta_5$ integrins are absent or expressed at low levels in normal endothelial cells but are induced in angiogenic vasculature of tumors (Brooks PC, Clark RA, Cheresh DA. *Science*, 264: 569-571, 1994, 1994; Hammes HP, Brownlee M, Jonczyk A, Sutter A, and Preissner KT. *Nature Med.* 2: 529-533, 1996.). Aminopeptidase N/CD13 has recently been identified as an angiogenic receptor for the NGR motif (Burg, M.A., *et al. Cancer Res.* 59, 2869-2874, 1999.). Aminopeptidase N/CD13 is strongly expressed not only in the angiogenic blood vessels of prostate cancer in TRAMP mice but also in the normal epithelial prostate tissue.

[0084] Tumor-homing phage co-localize with their receptors in the angiogenic vasculature of tumors but not in non-angiogenic blood vessels in normal tissues (Arap *et al.*, 1998b). Immunohistochemical evidence shows that vascular targeting phage bind to human tumor blood vessels in tissue sections (Pasqualini *et al.*, 2000) but not to normal blood vessels. A negative control phage with no insert (fd phage) did not bind to normal or tumor tissue sections. The expression of the angiogenic receptors was evaluated in

cell lines, in non-proliferating blood vessels and in activated blood vessels of tumors and other angiogenic tissues such as corpus luteum. Flow cytometry and immunohistochemistry showed that these receptors are expressed in a number of tumor cells and in activated HUVECs (data not shown). The angiogenic receptors were not detected in the vasculature of normal organs of mouse or human tissues.

[0085] The distribution of these receptors was analyzed by immunohistochemistry in tumor cells, tumor vasculature, and normal vasculature. Alpha v integrins, CD13, aminopeptidase A, NG2, and MMP-2/MMP-9 - the known receptors in tumor blood vessels - are specifically expressed in angiogenic endothelial cells and pericytes of both human and murine origin. Angiogenic neovasculature expresses markers that are either expressed at very low levels or not at all in non-proliferating endothelial cells (not shown).

[0086] The markers of angiogenic endothelium include receptors for vascular growth factors, such as specific subtypes of VEGF and basic FGF receptors, and α_v integrins, among many others (Mustonen T and Alitalo K. *J. Cell Biol.* **129**:895-898, 1995.). Thus far, identification and isolation of novel molecules characteristic of angiogenic vasculature has been slow, mainly because endothelial cells undergo dramatic phenotypic changes when grown in culture (Watson *et al.*, *Science*, **268**:447-448, 1995).

[0087] Many of these tumor vascular markers are proteases and some of the markers also serve as viral receptors. Alpha v integrins are receptors for adenoviruses (Wickham *et al.*, *Cancer Immunol. Immunother.* **45**:149-151, 1997c) and CD13 is a receptor for coronaviruses (Look *et al.* *N. J. Clin. Invest.* **83**:1299-1307, 1989.). MMP-2 and MMP-9 are receptors for echoviruses (Koivunen *et al.*, 1999a). Aminopeptidase A also appears to be a viral receptor. Bacteriophage may use the same cellular receptors as eukaryotic viruses. These findings suggest that receptors isolated by *in vivo* phage display will have cell internalization capability, a key feature for utilizing the identified peptide motifs as targeted gene therapy carriers.

Targeted delivery

[0088] Peptides that home to tumor vasculature have been coupled to cytotoxic drugs or proapoptotic peptides to yield compounds that were more effective and less toxic than the parental compounds in experimental models of mice bearing tumor xenografts (Arap

et al., 1998a; Ellerby *et al.*, 1999). The insertion of the RGD-4C peptide into a surface protein of an adenovirus has produced an adenoviral vector that may be used for tumor targeted gene therapy (Arap *et al.*, 1998b).

BRASIL

[0089] In preferred embodiments, separation of phage bound to the cells of a target organ, tissue or cell type from unbound phage is achieved using the BRASIL technique (PCT Patent Application PCT/US01/28124 entitled, "Biopanning and Rapid Analysis of Selective Interactive Ligands (BRASIL)" by Arap *et al.*, filed September 7, 2001, incorporated herein by reference in its entirety). In BRASIL (Biopanning and Rapid Analysis of Soluble Interactive Ligands), an organ, tissue or cell type is gently separated into cells or small clumps of cells that are suspended in an aqueous phase. The aqueous phase is layered over an organic phase of appropriate density and centrifuged. Cells attached to bound phage are pelleted at the bottom of the centrifuge tube, while unbound phage remain in the aqueous phase. This allows a more efficient separation of bound from unbound phage, while maintaining the binding interaction between phage and cell. BRASIL may be performed in an *in vivo* protocol, in which organs, tissues or cell types are exposed to a phage display library by intravenous administration, or by an *ex vivo* protocol, where the cells are exposed to the phage library in the aqueous phase before centrifugation.

Preparation of large scale primary libraries

[0090] In certain embodiments, primary phage libraries are amplified before injection into a human subject. A phage library is prepared by ligating targeting peptide-encoding sequences into a phage vector, such as fUSE5. The vector is transformed into pilus negative host *E. coli* such as strain MC1061. The bacteria are grown overnight and then aliquots are frozen to provide stock for library production. Use of pilus negative bacteria avoids the bias in libraries that arises from differential infection of pilus positive bacteria by different targeting peptide sequences.

[0091] To freeze, bacteria are pelleted from two thirds of a primary library culture (5 liters) at 4000 x g for 10 min. Bacteria are resuspended and washed twice with 500 ml of 10% glycerol in water, then frozen in an ethanol/dry ice bath and stored at -80°C.

[0100] For amplification, 1.5 ml of frozen bacteria are inoculated into 5 liters of LB medium with 20 µg/ml tetracycline and grown overnight. Thirty minutes after inoculation, a serial dilution is plated on LB/tet plates to verify the viability of the culture. If the number of viable bacteria is less than 5-10 times the number of individual clones in the library ($1-2 \times 10^8$) the culture is discarded.

[0101] After growing the bacterial culture overnight, phage are precipitated. About 1/4 to 1/3 of the bacterial culture is kept growing overnight in 5 liters of fresh medium and the cycle is repeated up to 5 times. Phage are pooled from all cycles and used for injection into human subjects.

Human Subjects

[0102] The methods used for phage display biopanning in the mouse model system require substantial improvements for use with humans. Techniques for biopanning in human subjects are disclosed in PCT Patent Application PCT/US01/28044, filed September 7, 2001, the entire text of which is incorporated herein by reference. In general, humans suitable for use with phage display are either brain dead or terminal wean patients. The amount of phage library (preferably primary library) required for administration must be significantly increased, preferably to 10^{14} TU or higher, preferably administered intravenously in approximately 200 ml of Ringer lactate solution over about a 10 minute period.

[0103] The amount of phage required for use in humans has required substantial improvement of the mouse protocol, increasing the amount of phage available for injection by five orders of magnitude. To produce such large phage libraries, the transformed bacterial pellets recovered from up to 500 to 1000 transformations are amplified up to 10 times in the bacterial host, recovering the phage from each round of amplification and adding LB Tet medium to the bacterial pellet for collection of additional phage. The phage inserts remain stable under these conditions and phage may be pooled to form the large phage display library required for humans.

[0104] Samples of various organs and tissues are collected starting approximately 15 minutes after injection of the phage library. Samples are processed as described below and phage collected from each organ, tissue or cell type of interest for DNA sequencing to determine the amino acid sequences of targeting peptides.

[0105] With humans, the opportunities for enrichment by multiple rounds of biopanning are severely restricted, compared to the mouse model system. A substantial improvement in the biopanning technique involves polyorgan targeting.

Polyorgan targeting

[0106] In the standard protocol for phage display biopanning, phage from a single organ are collected, amplified and injected into a new host, where tissue from the same organ is collected for phage rescue and a new round of biopanning. This protocol is feasible in animal subjects. However, the limited availability and expense of processing samples from humans requires an improvement in the protocol.

[0107] It is possible to pool phage collected from multiple organs after a first round of biopanning and inject the pooled sample into a new subject, where each of the multiple organs may be collected again for phage rescue. The polyorgan targeting protocol may be repeated for as many rounds of biopanning as desired. In this manner, it is possible to significantly reduce the number of subjects required for isolation of targeting peptides for multiple organs, while still achieving substantial enrichment of the organ-homing phage.

[0108] In preferred embodiments, phage are recovered from human organs, tissues or cell types after injection of a phage display library into a human subject. In certain embodiments, phage may be recovered by exposing a sample of the organ, tissue or cell type to a pilus positive bacterium, such as *E. coli* K91. In alternative embodiments, phage may be recovered by amplifying the phage inserts, ligating the inserts to phage DNA and producing new phage from the ligated DNA.

Proteins and Peptides

[0109] In certain embodiments, the present invention concerns novel compositions comprising at least one protein or peptide. As used herein, a protein or peptide generally refers, but is not limited to, a protein of greater than about 200 amino acids, up to a full length sequence translated from a gene; a polypeptide of greater than about 100 amino acids; and/or a peptide of from about 3 to about 100 amino acids. For convenience, the terms "protein," "polypeptide" and "peptide are used interchangeably herein.

[0110] In certain embodiments the size of at least one protein or peptide may comprise, but is not limited to, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, about 110, about 120, about 130, about 140, about 150, about 160, about 170, about 180, about 190, about 200, about 210, about 220, about 230, about 240, about 250, about 275, about 300, about 325, about 350, about 375, about 400, about 425, about 450, about 475, about 500, about 525, about 550, about 575, about 600, about 625, about 650, about 675, about 700, about 725, about 750, about 775, about 800, about 825, about 850, about 875, about 900, about 925, about 950, about 975, about 1000, about 1100, about 1200, about 1300, about 1400, about 1500, about 1750, about 2000, about 2250, about 2500 or greater amino acid residues.

[0111] As used herein, an "amino acid residue" refers to any naturally occurring amino acid, any amino acid derivative or any amino acid mimic known in the art. In certain embodiments, the residues of the protein or peptide are sequential, without any non-amino acid interrupting the sequence of amino acid residues. In other embodiments, the sequence may comprise one or more non-amino acid moieties. In particular embodiments, the sequence of residues of the protein or peptide may be interrupted by one or more non-amino acid moieties.

[0112] Accordingly, the term "protein or peptide" encompasses amino acid sequences comprising at least one of the 20 common amino acids found in naturally occurring proteins, or at least one modified or unusual amino acid, including but not limited to those shown on Table 1 below.

TABLE 1

Modified and Unusual Amino Acids

Abbr.	Amino Acid	Abbr.	Amino Acid
Aad	2-Aminoadipic acid	EtAsn	N-Ethylasparagine
Baad	3-Aminoadipic acid	Hyl	Hydroxylysine
Bala	β -alanine, β -Amino-propionic acid	AHyl	allo-Hydroxylysine
Abu	2-Aminobutyric acid	3Hyp	3-Hydroxyproline
4Abu	4-Aminobutyric acid, piperidinic acid	4Hyp	4-Hydroxyproline
Acp	6-Aminocaproic acid	Idc	Isodesmosine
Ahe	2-Aminoheptanoic acid	Alle	allo-Isoleucine
Aib	2-Aminoisobutyric acid	MeGly	N-Methylglycine, sarcosine
Baib	3-Aminoisobutyric acid	MeIle	N-Methylisoleucine
Aprm	2-Aminopimelic acid	MeLys	6-N-Methyllysine
Dbu	2,4-Diaminobutyric acid	MeVal	N-Methylvaline
Des	Desmosine	Nva	Norvaline
Dpm	2,2'-Diaminopimelic acid	Nle	Norleucine
Dpr	2,3-Diaminopropionic acid	Orn	Ornithine
EtGly	N-Ethylglycine		

[0113] Proteins or peptides may be made by any technique known to those of skill in the art, including the expression of proteins, polypeptides or peptides through standard molecular biological techniques, the isolation of proteins or peptides from natural sources, or the chemical synthesis of proteins or peptides. The nucleotide and protein, polypeptide and peptide sequences corresponding to various genes have been previously disclosed, and may be found at computerized databases known to those of ordinary skill in the art. One such database is the National Center for Biotechnology Information's Genbank and GenPept databases (<http://www.ncbi.nlm.nih.gov/>). The coding regions for known genes may be amplified and/or expressed using the techniques disclosed herein or as would be known to those of ordinary skill in the art. Alternatively, various commercial preparations of proteins, polypeptides and peptides are known to those of skill in the art.

Peptide mimetics

[0114] Another embodiment for the preparation of polypeptides according to the invention is the use of peptide mimetics. Mimetics are peptide-containing molecules that mimic elements of protein secondary structure. See, for example, Johnson *et al.*, "Peptide Turn Mimetics" in *BIOTECHNOLOGY AND PHARMACY*, Pezzuto *et al.*, Eds., Chapman and Hall, New York (1993), incorporated herein by reference. The underlying rationale behind the use of peptide mimetics is that the peptide backbone of proteins exists chiefly to orient amino acid side chains in such a way as to facilitate molecular interactions, such as those of antibody and antigen. A peptide mimetic is expected to permit molecular interactions similar to the natural molecule. These principles may be used to engineer second generation molecules having many of the natural properties of the targeting peptides disclosed herein, but with altered and even improved characteristics.

Fusion proteins

[0115] Other embodiments of the present invention concern fusion proteins. These molecules generally have all or a substantial portion of a targeting peptide, linked at the N- or C-terminus, to all or a portion of a second polypeptide or protein. For example, fusions may employ leader sequences from other species to permit the recombinant expression of a protein in a heterologous host. Another useful fusion includes the addition of an immunologically active domain, such as an antibody epitope, to facilitate purification of the fusion protein. Inclusion of a cleavage site at or near the fusion junction will facilitate removal of the extraneous polypeptide after purification. Other useful fusions include linking of functional domains, such as active sites from enzymes, glycosylation domains, cellular targeting signals or transmembrane regions. In preferred embodiments, the fusion proteins of the instant invention comprise a targeting peptide linked to a therapeutic protein or peptide. Examples of proteins or peptides that may be incorporated into a fusion protein include cytostatic proteins, cytotoxic proteins, pro-apoptosis agents, anti-angiogenic agents, hormones, cytokines, growth factors, peptide drugs, antibodies, Fab fragments antibodies, antigens, receptor proteins, enzymes, lectins, MHC proteins, cell adhesion proteins and binding proteins. These examples are not meant to be limiting and it is contemplated that within the scope of the present

invention virtually and protein or peptide could be incorporated into a fusion protein comprising a targeting peptide. Methods of generating fusion proteins are well known to those of skill in the art. Such proteins can be produced, for example, by chemical attachment using bifunctional cross-linking reagents, by *de novo* synthesis of the complete fusion protein, or by attachment of a DNA sequence encoding the targeting peptide to a DNA sequence encoding the second peptide or protein, followed by expression of the intact fusion protein.

Protein purification

[0116] In certain embodiments a protein or peptide may be isolated or purified. Protein purification techniques are well known to those of skill in the art. These techniques involve, at one level, the homogenization and crude fractionation of the cells, tissue or organ to polypeptide and non-polypeptide fractions. The protein or polypeptide of interest may be further purified using chromatographic and electrophoretic techniques to achieve partial or complete purification (or purification to homogeneity). Analytical methods particularly suited to the preparation of a pure peptide are ion-exchange chromatography, gel exclusion chromatography, polyacrylamide gel electrophoresis, affinity chromatography, immunoaffinity chromatography and isoelectric focusing. An example of receptor protein purification by affinity chromatography is disclosed in U.S. Patent No. 5,206,347, the entire text of which is incorporated herein by reference. A particularly efficient method of purifying peptides is fast performance liquid chromatography (FPLC) or even high performance liquid chromatography (HPLC).

[0117] A purified protein or peptide is intended to refer to a composition, isolatable from other components, wherein the protein or peptide is purified to any degree relative to its naturally-obtainable state. An isolated or purified protein or peptide, therefore, also refers to a protein or peptide free from the environment in which it may naturally occur. Generally, "purified" will refer to a protein or peptide composition that has been subjected to fractionation to remove various other components, and which composition substantially retains its expressed biological activity. Where the term "substantially purified" is used, this designation will refer to a composition in which the protein or peptide forms the major component of the composition, such as constituting about 50%,

about 60%, about 70%, about 80%, about 90%, about 95%, or more of the proteins in the composition.

[0118] Various methods for quantifying the degree of purification of the protein or peptide are known to those of skill in the art in light of the present disclosure. These include, for example, determining the specific activity of an active fraction, or assessing the amount of polypeptides within a fraction by SDS/PAGE analysis. A preferred method for assessing the purity of a fraction is to calculate the specific activity of the fraction, to compare it to the specific activity of the initial extract, and to thus calculate the degree of purity therein, assessed by a "fold purification number." The actual units used to represent the amount of activity will, of course, be dependent upon the particular assay technique chosen to follow the purification, and whether or not the expressed protein or peptide exhibits a detectable activity.

[0119] Various techniques suitable for use in protein purification are well known to those of skill in the art. These include, for example, precipitation with ammonium sulphate, PEG, antibodies and the like, or by heat denaturation, followed by: centrifugation; chromatography steps such as ion exchange, gel filtration, reverse phase, hydroxylapatite and affinity chromatography; isoelectric focusing; gel electrophoresis; and combinations of these and other techniques. As is generally known in the art, it is believed that the order of conducting the various purification steps may be changed, or that certain steps may be omitted, and still result in a suitable method for the preparation of a substantially purified protein or peptide.

[0120] There is no general requirement that the protein or peptide always be provided in their most purified state. Indeed, it is contemplated that less substantially purified products will have utility in certain embodiments. Partial purification may be accomplished by using fewer purification steps in combination, or by utilizing different forms of the same general purification scheme. For example, it is appreciated that a cation-exchange column chromatography performed utilizing an HPLC apparatus will generally result in a greater "fold" purification than the same technique utilizing a low pressure chromatography system. Methods exhibiting a lower degree of relative purification may have advantages in total recovery of protein product, or in maintaining the activity of an expressed protein.

[0121] Affinity chromatography is a chromatographic procedure that relies on the specific affinity between a substance to be isolated and a molecule to which it can specifically bind. This is a receptor-ligand type of interaction. The column material is synthesized by covalently coupling one of the binding partners to an insoluble matrix. The column material is then able to specifically adsorb the substance from the solution. Elution occurs by changing the conditions to those in which binding will not occur (*e.g.*, altered pH, ionic strength, temperature, *etc.*). The matrix should be a substance that itself does not adsorb molecules to any significant extent and that has a broad range of chemical, physical and thermal stability. The ligand should be coupled in such a way as to not affect its binding properties. The ligand should also provide relatively tight binding. And it should be possible to elute the substance without destroying the sample or the ligand.

Synthetic Peptides

[0122] Because of their relatively small size, the targeting peptides of the invention can be synthesized in solution or on a solid support in accordance with conventional techniques. Various automatic synthesizers are commercially available and can be used in accordance with known protocols. See, for example, Stewart and Young, *Solid Phase Peptide Synthesis*, 2d ed. Pierce Chemical Co., 1984; Tam *et al.*, *J. Am. Chem. Soc.*, 105:6442, 1983; Merrifield, *Science*, 232: 341-347, 1986; and Barany and Merrifield, *The Peptides*, Gross and Meienhofer, eds., Academic Press, New York, pp. 1-284, 1979, each incorporated herein by reference. Short peptide sequences, usually from about 6 up to about 35 to 50 amino acids, can be readily synthesized by such methods. Alternatively, recombinant DNA technology may be employed wherein a nucleotide sequence which encodes a peptide of the invention is inserted into an expression vector, transformed or transfected into an appropriate host cell, and cultivated under conditions suitable for expression.

Antibodies

[0123] In certain embodiments, it may be desirable to make antibodies against the identified targeting peptides or their receptors. The appropriate targeting peptide or receptor, or portions thereof, may be coupled, bonded, bound, conjugated, or chemically-linked to one or more agents via linkers, polylinkers, or derivatized amino acids. This

may be performed such that a bispecific or multivalent composition or vaccine is produced. It is further envisioned that the methods used in the preparation of these compositions are familiar to those of skill in the art and should be suitable for administration to humans, *i.e.*, pharmaceutically acceptable. Preferred agents are the carriers are keyhole limpet hemocyanin (KLH) or bovine serum albumin (BSA).

[0124] The term "antibody" is used to refer to any antibody-like molecule that has an antigen binding region, and includes antibody fragments such as Fab', Fab, F(ab')₂, single domain antibodies (DABs), Fv, scFv (single chain Fv), and the like. Techniques for preparing and using various antibody-based constructs and fragments are well known in the art. Means for preparing and characterizing antibodies are also well known in the art (See, *e.g.*, Harlow and Lane, Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory, 1988; incorporated herein by reference).

Cytokines and chemokines

[0125] In certain embodiments, it may be desirable to couple specific bioactive agents to one or more targeting peptides for targeted delivery to an organ, tissue or cell type. Such agents include, but are not limited to, cytokines, chemokines, pro-apoptosis factors and anti-angiogenic factors. The term "cytokine" is a generic term for proteins released by one cell population that act on another cell as intercellular mediators.

[0126] Examples of such cytokines are lymphokines, monokines, growth factors and traditional polypeptide hormones. Included among the cytokines are growth hormones such as human growth hormone, N-methionyl human growth hormone, and bovine growth hormone; parathyroid hormone; thyroxine; insulin; proinsulin; relaxin; prolaxin; glycoprotein hormones such as follicle stimulating hormone (FSH), thyroid stimulating hormone (TSH), and luteinizing hormone (LH); hepatic growth factor; prostaglandin, fibroblast growth factor; prolactin; placental lactogen, OB protein; tumor necrosis factor- α . and - β .; mullerian-inhibiting substance; mouse gonadotropin-associated peptide; inhibin; activin; vascular endothelial growth factor; integrin; thrombopoietin (TPO); nerve growth factors such as NGF- β .; platelet-growth factor; transforming growth factors (TGFs) such as TGF- α . and TGF- β .; insulin-like growth factor-I and -II; erythropoietin (EPO); osteoinductive factors; interferons such as interferon- α , - β , and - γ ; colony stimulating factors (CSFs) such as macrophage-CSF (M-

CSF); granulocyte-macrophage-CSF (GM-CSF); and granulocyte-CSF (G-CSF); interleukins (ILs) such as IL-1, IL-1.alpha., IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-11, IL-12; IL-13, IL-14, IL-15, IL-16, IL-17, IL-18, LIF, G-CSF, GM-CSF, M-CSF, EPO, kit-ligand or FLT-3, angiostatin, thrombospondin, endostatin, tumor necrosis factor and LT. As used herein, the term cytokine includes proteins from natural sources or from recombinant cell culture and biologically active equivalents of the native sequence cytokines.

[0127] Chemokines generally act as chemoattractants to recruit immune effector cells to the site of chemokine expression. It may be advantageous to express a particular chemokine gene in combination with, for example, a cytokine gene, to enhance the recruitment of other immune system components to the site of treatment. Chemokines include, but are not limited to, RANTES, MCAF, MIP1-alpha, MIP1-Beta, and IP-10. The skilled artisan will recognize that certain cytokines are also known to have chemoattractant effects and could also be classified under the term chemokines.

Imaging agents and radioisotopes

[0128] In certain embodiments, the claimed peptides or proteins of the present invention may be attached to imaging agents of use for imaging and diagnosis of various diseased organs, tissues or cell types. Many appropriate imaging agents are known in the art, as are methods for their attachment to proteins or peptides (see, e.g., U.S. patents 5,021,236 and 4,472,509, both incorporated herein by reference). Certain attachment methods involve the use of a metal chelate complex employing, for example, an organic chelating agent such a DTPA attached to the protein or peptide (U.S. Patent 4,472,509). Proteins or peptides also may be reacted with an enzyme in the presence of a coupling agent such as glutaraldehyde or periodate. Conjugates with fluorescein markers are prepared in the presence of these coupling agents or by reaction with an isothiocyanate.

[0129] Non-limiting examples of paramagnetic ions of potential use as imaging agents include chromium (III), manganese (II), iron (III), iron (II), cobalt (II), nickel (II), copper (II), neodymium (III), samarium (III), ytterbium (III), gadolinium (III), vanadium (II), terbium (III), dysprosium (III), holmium (III) and erbium (III), with gadolinium being particularly preferred. Ions useful in other contexts, such as X-ray imaging,

include but are not limited to lanthanum (III), gold (III), lead (II), and especially bismuth (III).

[0130] Radioisotopes of potential use as imaging or therapeutic agents include astatine²¹¹, ¹⁴carbon, ⁵¹chromium, ³⁶chlorine, ⁵⁷cobalt, ⁵⁸cobalt, copper⁶⁷, ¹⁵²Eu, gallium⁶⁷, ³hydrogen, iodine¹²³, iodine¹²⁵, iodine¹³¹, indium¹¹¹, ⁵⁹iron, ³²phosphorus, rhenium¹⁸⁶, rhenium¹⁸⁸, ⁷⁵selenium, ³⁵sulphur, technetium^{99m} and yttrium⁹⁰. ¹²⁵I is often being preferred for use in certain embodiments, and technetium^{99m} and indium¹¹¹ are also often preferred due to their low energy and suitability for long range detection.

[0131] Radioactively labeled proteins or peptides of the present invention may be produced according to well-known methods in the art. For instance, they can be iodinated by contact with sodium or potassium iodide and a chemical oxidizing agent such as sodium hypochlorite, or an enzymatic oxidizing agent, such as lactoperoxidase. Proteins or peptides according to the invention may be labeled with technetium-^{99m} by ligand exchange process, for example, by reducing pertechnetate with stannous solution, chelating the reduced technetium onto a Sephadex column and applying the peptide to this column or by direct labeling techniques, *e.g.*, by incubating pertechnetate, a reducing agent such as SnCl_2 , a buffer solution such as sodium-potassium phthalate solution, and the peptide. Intermediary functional groups that are often used to bind radioisotopes that exist as metallic ions to peptides are diethylenetriaminepenta-acetic acid (DTPA) and ethylene diaminetetra-acetic acid (EDTA). Also contemplated for use are fluorescent labels, including rhodamine, fluorescein isothiocyanate and renograffin.

[0132] In certain embodiments, the claimed proteins or peptides may be linked to a secondary binding ligand or to an enzyme (an enzyme tag) that will generate a colored product upon contact with a chromogenic substrate. Examples of suitable enzymes include urease, alkaline phosphatase, (horseradish) hydrogen peroxidase and glucose oxidase. Preferred secondary binding ligands are biotin and avidin or streptavidin compounds. The use of such labels is well known to those of skill in the art in light and is described, for example, in U.S. Patents 3,817,837; 3,850,752; 3,939,350; 3,996,345; 4,277,437; 4,275,149 and 4,366,241; each incorporated herein by reference.

Cross-linkers

[0133] Bifunctional cross-linking reagents have been extensively used for a variety of purposes including preparation of affinity matrices, modification and stabilization of diverse structures, identification of ligand and receptor binding sites, and structural studies. Homobifunctional reagents that carry two identical functional groups proved to be highly efficient in inducing cross-linking between identical and different macromolecules or subunits of a macromolecule, and linking of polypeptide ligands to their specific binding sites. Heterobifunctional reagents contain two different functional groups. By taking advantage of the differential reactivities of the two different functional groups, cross-linking can be controlled both selectively and sequentially. The bifunctional cross-linking reagents can be divided according to the specificity of their functional groups, *e.g.*, amino, sulfhydryl, guanidino, indole, carboxyl specific groups. Of these, reagents directed to free amino groups have become especially popular because of their commercial availability, ease of synthesis and the mild reaction conditions under which they can be applied. A majority of heterobifunctional cross-linking reagents contains a primary amine-reactive group and a thiol-reactive group.

[0134] Exemplary methods for cross-linking ligands to liposomes are described in U.S. Patent 5,603,872 and U.S. Patent 5,401,511, each specifically incorporated herein by reference in its entirety). Various ligands can be covalently bound to liposomal surfaces through the cross-linking of amine residues. Liposomes, in particular, multilamellar vesicles (MLV) or unilamellar vesicles such as microemulsified liposomes (MEL) and large unilamellar liposomes (LUVET), each containing phosphatidylethanolamine (PE), have been prepared by established procedures. The inclusion of PE in the liposome provides an active functional residue, a primary amine, on the liposomal surface for cross-linking purposes. Ligands such as epidermal growth factor (EGF) have been successfully linked with PE-liposomes. Ligands are bound covalently to discrete sites on the liposome surfaces. The number and surface density of these sites are dictated by the liposome formulation and the liposome type. The liposomal surfaces may also have sites for non-covalent association. To form covalent conjugates of ligands and liposomes, cross-linking reagents have been studied for effectiveness and biocompatibility. Cross-linking reagents include glutaraldehyde

(GAD), bifunctional oxirane (OXR), ethylene glycol diglycidyl ether (EGDE), and a water soluble carbodiimide, preferably 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC). Through the complex chemistry of cross-linking, linkage of the amine residues of the recognizing substance and liposomes is established.

[0135] In another example, heterobifunctional cross-linking reagents and methods of using the cross-linking reagents are described (U.S. Patent 5,889,155, specifically incorporated herein by reference in its entirety). The cross-linking reagents combine a nucleophilic hydrazide residue with an electrophilic maleimide residue, allowing coupling in one example, of aldehydes to free thiols. The cross-linking reagent can be modified to cross-link various functional groups.

Nucleic Acids

[0136] Nucleic acids according to the present invention may encode a targeting peptide, a receptor protein, a fusion protein or other protein or peptide. The nucleic acid may be derived from genomic DNA, complementary DNA (cDNA) or synthetic DNA. Where incorporation into an expression vector is desired, the nucleic acid may also comprise a natural intron or an intron derived from another gene. Such engineered molecules are sometime referred to as "mini-genes."

[0137] A "nucleic acid" as used herein includes single-stranded and double-stranded molecules, as well as DNA, RNA, chemically modified nucleic acids and nucleic acid analogs. It is contemplated that a nucleic acid within the scope of the present invention may be of almost any size, determined in part by the length of the encoded protein or peptide.

[0138] It is contemplated that targeting peptides, fusion proteins and receptors may be encoded by any nucleic acid sequence that encodes the appropriate amino acid sequence. The design and production of nucleic acids encoding a desired amino acid sequence is well known to those of skill in the art, using standardized codon tables (see Table 2 below). In preferred embodiments, the codons selected for encoding each amino acid may be modified to optimize expression of the nucleic acid in the host cell of interest. Codon preferences for various species of host cell are well known in the art.

TABLE 2

Amino Acid			Codons			
Alanine	Ala	A	GCA	GCC	GCG	GCU
Cysteine	Cys	C	UGC	UGU		
Aspartic acid	Asp	D	GAC	GAU		
Glutamic acid	Glu	E	GAA	GAG

Valine	Val	V	GUA	GUC	GUG	GUU
Tryptophan	Trp	W	UGG			
Tyrosine	Tyr	Y	UAC	UAU		

[0139] In addition to nucleic acids encoding the desired peptide or protein, the present invention encompasses complementary nucleic acids that hybridize under high stringency conditions with such coding nucleic acid sequences. High stringency conditions for nucleic acid hybridization are well known in the art. For example, conditions may comprise low salt and/or high temperature conditions, such as provided by about 0.02 M to about 0.15 M NaCl at temperatures of about 50°C to about 70°C. It is understood that the temperature and ionic strength of a desired stringency are determined in part by the length of the particular nucleic acid(s), the length and nucleotide content of the target sequence(s), the charge composition of the nucleic acid(s), and to the presence or concentration of formamide, tetramethylammonium chloride or other solvent(s) in a hybridization mixture.

Vectors for Cloning, Gene Transfer and Expression

[0140] In certain embodiments expression vectors are employed to express the targeting peptide or fusion protein, which can then be purified and used. In other embodiments, the expression vectors are used in gene therapy. Expression requires that appropriate signals be provided in the vectors, and which include various regulatory elements, such as enhancers/promoters from both viral and mammalian sources that drive expression of the genes of interest in host cells. Elements designed to optimize messenger RNA stability and translatability in host cells also are known.

Regulatory Elements

[0141] The terms "expression construct" or "expression vector" are meant to include any type of genetic construct containing a nucleic acid coding for a gene product in which part or all of the nucleic acid coding sequence is capable of being transcribed. In preferred embodiments, the nucleic acid encoding a gene product is under transcriptional control of a promoter. A "promoter" refers to a DNA sequence recognized by the synthetic machinery of the cell, or introduced synthetic machinery, required to initiate the specific transcription of a gene. The phrase "under transcriptional control" means that the promoter is in the correct location and orientation in relation to the nucleic acid to control RNA polymerase initiation and expression of the gene.

[0142] The particular promoter employed to control the expression of a nucleic acid sequence of interest is not believed to be important, so long as it is capable of directing the expression of the nucleic acid in the targeted cell. Thus, where a human cell is targeted, it is preferable to position the nucleic acid coding region adjacent and under the control of a promoter that transcriptionally active in human cells. Generally speaking, such a promoter might include either a human or viral promoter.

[0143] In various embodiments, the human cytomegalovirus (CMV) immediate early gene promoter, the SV40 early promoter, the Rouse sarcoma virus long terminal repeat, rat insulin promoter, and glyceraldehyde-3-phosphate dehydrogenase promoter can be used to obtain high-level expression of the coding sequence of interest. The use of other viral or mammalian cellular or bacterial phage promoters that are well-known in the art to achieve expression of a coding sequence of interest is contemplated as well, provided that the levels of expression are sufficient for a given purpose.

[0144] Where a cDNA insert is employed, one will typically include a polyadenylation signal to effect proper polyadenylation of the gene transcript. The nature of the polyadenylation signal is not believed to be crucial to the successful practice of the invention, and any such sequence may be employed, such as human growth hormone and SV40 polyadenylation signals. Also contemplated as an element of the expression construct is a terminator. These elements can serve to enhance message levels and to minimize read through from the construct into other sequences.

Selectable Markers

[0145] In certain embodiments of the invention, the cells containing nucleic acid constructs of the present invention may be identified *in vitro* or *in vivo* by including a marker in the expression construct. Such markers would confer an identifiable change to the cell permitting easy identification of cells containing the expression construct. Usually the inclusion of a drug selection marker aids in cloning and in the selection of transformants. For example, genes that confer resistance to neomycin, puromycin, hygromycin, DHFR, GPT, zeocin, and histidinol are useful selectable markers. Alternatively, enzymes such as herpes simplex virus thymidine kinase (*tk*) or chloramphenicol acetyltransferase (CAT) may be employed. Immunologic markers also can be employed. The selectable marker employed is not believed to be important, so long as it is capable of being expressed simultaneously with the nucleic acid encoding a gene product. Further examples of selectable markers are well known to one of skill in the art.

Delivery of Expression Vectors

[0146] There are a number of ways in which expression vectors may be introduced into cells. In certain embodiments of the invention, the expression construct comprises a virus or engineered construct derived from a viral genome. The ability of certain viruses to enter cells via receptor-mediated endocytosis, to integrate into host cell genome, and express viral genes stably and efficiently have made them attractive candidates for the transfer of foreign genes into mammalian cells (Ridgeway, 1988; Nicolas and Rubinstein, *In: Vectors: A survey of molecular cloning vectors and their uses*, Rodriguez and Denhardt, eds., Stoneham: Butterworth, pp. 494-513, 1988.; Baichwal and Sugden, Baichwal, *In: Gene Transfer*, Kucherlapati R, ed., New York, Plenum Press, pp. 117-148,

1986. 1986; Temin, In: *Gene Transfer*, Kucherlapati, R. ed., New York, Plenum Press, pp. 149-188, 1986). Preferred gene therapy vectors are generally viral vectors.

[0147] In using viral delivery systems, one will desire to purify the virion sufficiently to render it essentially free of undesirable contaminants, such as defective interfering viral particles or endotoxins and other pyrogens such that it will not cause any untoward reactions in the cell, animal or individual receiving the vector construct. A preferred means of purifying the vector involves the use of buoyant density gradients, such as cesium chloride gradient centrifugation.

[0148] DNA viruses used as gene vectors include the papovaviruses (e.g., simian virus 40, bovine papilloma virus, and polyoma) (Ridgeway, pp 467-492, 1988; Baichwal and Sugden, 1986) and adenoviruses (Ridgeway, 1988; Baichwal and Sugden, 1986).

[0149] One of the preferred methods for *in vivo* delivery involves the use of an adenovirus expression vector. Although adenovirus vectors are known to have a low capacity for integration into genomic DNA, this feature is counterbalanced by the high efficiency of gene transfer afforded by these vectors. "Adenovirus expression vector" is meant to include, but is not limited to, constructs containing adenovirus sequences sufficient to (a) support packaging of the construct and (b) to express an antisense or a sense polynucleotide that has been cloned therein.

[0150] Generation and propagation of adenovirus vectors that are replication deficient depend on a unique helper cell line, designated 293, which is transformed from human embryonic kidney cells by Ad5 DNA fragments and constitutively expresses E1 proteins (Graham *et al.*, *J. Gen. Virol.*, 36:59-72, 1977.). Since the E3 region is dispensable from the adenovirus genome (Jones and Shenk, *Cell*, 13:181-188, 1978), the current adenovirus vectors, with the help of 293 cells, carry foreign DNA in either the E1, the E3, or both regions (Graham and Prevec, In: *Methods in Molecular Biology: Gene Transfer and Expression Protocol*, E.J. Murray, ed., Humana Press, Clifton, NJ, 7:109-128, 1991.).

[0151] Helper cell lines may be derived from human cells such as human embryonic kidney cells, muscle cells, hematopoietic cells or other human embryonic mesenchymal or epithelial cells. Alternatively, the helper cells may be derived from the cells of other mammalian species that are permissive for human adenovirus. Such cells include, e.g.,

Vero cells or other monkey embryonic mesenchymal or epithelial cells. As discussed, the preferred helper cell line is 293. Rancher *et al.*, (*Biotechnol. Tech.* 9:169-174, 1995) disclosed improved methods for culturing 293 cells and propagating adenovirus.

[0152] Adenovirus vectors have been used in eukaryotic gene expression (Levrero *et al.*, *Gene*, 101:195-202, 1991; Gomez-Foix *et al.*, *J. Biol. Chem.*, 267:25129-25134, 1992) and vaccine development (Grunhaus and Horwitz, 1992; Graham and Prevec, 1991). Animal studies have suggested that recombinant adenovirus could be used for gene therapy (Stratford-Perricaudet and Perricaudet, *In: Human Gene Transfer*, O. Cohen-Hagueneauer *et al.*, eds. John Libbey Eurotext, France, pp. 51-61, 1991; Stratford-Perricaudet *et al.*, *Hum. Gene Ther.* 1:241-256, 1990; Rich *et al.*, *Hum. Gene Ther.* 4:461-476, 1993). Studies in administering recombinant adenovirus to different tissues include trachea instillation (Rosenfeld *et al.*, *Science*, 252: 431-434, 1991; Rosenfeld *et al.*, *Cell*, 68: 143-155, 1992), muscle injection (Ragot *et al.*, *Nature*, 361:647-650, 1993), peripheral intravenous injections (Herz and Gerard, *Proc. Natl. Acad. Sci. USA*, 90:2812-2816, 1993) and stereotactic inoculation into the brain (Le Gal La Salle *et al.*, *Science*, 259:988-990, 1993).

[0153] Other gene transfer vectors may be constructed from retroviruses. (Coffin, *In: Virology*, Fields *et al.*, eds., Raven Press, New York, pp. 1437-1500, 1990.) The retroviral genome contains three genes, *gag*, *pol*, and *env*. that code for capsid proteins, polymerase enzyme, and envelope components, respectively. A sequence found upstream from the *gag* gene contains a signal for packaging of the genome into virions. Two long terminal repeat (LTR) sequences are present at the 5' and 3' ends of the viral genome. These contain strong promoter and enhancer sequences, and also are required for integration in the host cell genome (Coffin, 1990).

[0154] In order to construct a retroviral vector, a nucleic acid encoding protein of interest is inserted into the viral genome in the place of certain viral sequences to produce a virus that is replication-defective. In order to produce virions, a packaging cell line containing the *gag*, *pol*, and *env* genes, but without the LTR and packaging components, is constructed (Mann *et al.*, *Cell*, 33:153-159, 1983). When a recombinant plasmid containing a cDNA, together with the retroviral LTR and packaging sequences is introduced into this cell line (by calcium phosphate precipitation for example), the

packaging sequence allows the RNA transcript of the recombinant plasmid to be packaged into viral particles, which are then secreted into the culture media (Nicolas and Rubenstein, 1988; Temin, 1986; Mann *et al.*, 1983). The media containing the recombinant retroviruses is then collected, optionally concentrated, and used for gene transfer. Retroviral vectors are capable of infecting a broad variety of cell types. However, integration and stable expression require the division of host cells (Paskind *et al.*, *Virology*, 67:242-248, 1975).

[0155] Other viral vectors may be employed as expression constructs. Vectors derived from viruses such as vaccinia virus (Ridgeway, 1988; Baichwal and Sugden, 1986; Coupar *et al.*, *Gene* 68:1-10, 1988), adeno-associated virus (AAV) (Ridgeway, 1988; Baichwal and Sugden, 1986; Hermonat and Muzycska, *Proc. Natl. Acad. Sci. USA*, 81: 6466-6470, 1984), and herpes viruses may be employed. They offer several attractive features for various mammalian cells (Friedmann, *Science*, 244:1275-1281, 1989; Ridgeway, 1988; Baichwal and Sugden, 1986; Coupar *et al.*, 1988; Horwich *et al.*, *J. Virol.*, 64:642-650, 1990).

[0156] Several non-viral methods for the transfer of expression constructs into cultured mammalian cells also are contemplated by the present invention. These include calcium phosphate precipitation (Graham and van der Eb, *Virology*, 52:456-467, 1973.; Chen and Okayama, *Mol. Cell Biol.*, 7:2745-2752, 1987.; Rippe *et al.*, *Mol. Cell Biol.* 10: 689-695, 1990; DEAE dextran (Gopal, *et al. Mol. Cell Biol.*, 5:1188-1190, 1985), electroporation (Tur-Kaspa *et al.*, *Mol. Cell Biol.*, 6:716-718, 1986; Potter *et al.*, *Proc. Natl. Acad. Sci. USA*, 81: 7161-7165, 1984), direct microinjection, DNA-loaded liposomes and lipofectamine-DNA complexes, cell sonication, gene bombardment using high velocity microprojectiles, and receptor-mediated transfection (Wu and Wu, *J. Biol. Chem.* 262:4429-4432, 1987; Wu and Wu, *Biochemistry*, 27:887-892, 1988). Some of these techniques may be successfully adapted for *in vivo* or *ex vivo* use.

[0157] In a further embodiment of the invention, the expression construct may be entrapped in a liposome. Liposome-mediated nucleic acid delivery and expression of foreign DNA *in vitro* has been very successful. Wong *et al.*, (*Gene*, 10:87-94, 1980) demonstrated the feasibility of liposome-mediated delivery and expression of foreign DNA in cultured chick embryo, HeLa, and hepatoma cells. Nicolau *et al.*, (*Methods*

Enzymol., 149:157-176, 1987.) accomplished successful liposome-mediated gene transfer in rats after intravenous injection.

Pharmaceutical compositions

[0158] Where clinical applications are contemplated, it may be necessary to prepare pharmaceutical compositions - expression vectors, virus stocks, proteins, antibodies and drugs - in a form appropriate for the intended application. Generally, this will entail preparing compositions that are essentially free of impurities that could be harmful to humans or animals.

[0159] One generally will desire to employ appropriate salts and buffers to render delivery vectors stable and allow for uptake by target cells. Buffers also are employed when recombinant cells are introduced into a patient. Aqueous compositions of the present invention may comprise an effective amount of a protein, peptide, fusion protein, recombinant phage and/or expression vector, dissolved or dispersed in a pharmaceutically acceptable carrier or aqueous medium. Such compositions also are referred to as innocula. The phrase "pharmaceutically or pharmacologically acceptable" refers to molecular entities and compositions that do not produce adverse, allergic, or other untoward reactions when administered to an animal or a human. As used herein, "pharmaceutically acceptable carrier" includes any and all solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents and the like. The use of such media and agents for pharmaceutically active substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the proteins or peptides of the present invention, its use in therapeutic compositions is contemplated. Supplementary active ingredients also can be incorporated into the compositions.

[0160] The active compositions of the present invention may include classic pharmaceutical preparations. Administration of these compositions according to the present invention are via any common route so long as the target tissue is available via that route. This includes oral, nasal, buccal, rectal, vaginal or topical. Alternatively, administration may be by orthotopic, intradermal, subcutaneous, intramuscular, intraperitoneal, intraarterial or intravenous injection. Such compositions normally would be administered as pharmaceutically acceptable compositions, described *supra*.

[0161] The pharmaceutical forms suitable for injectable use include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. In all cases the form must be sterile and must be fluid to the extent that easy syringability exists. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms, such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), suitable mixtures thereof, and vegetable oils. The proper fluidity can be maintained, for example, by the use of a coating, such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. The prevention of the action of microorganisms can be brought about by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, thimerosal, and the like. In many cases, it is preferable to include isotonic agents, for example, sugars or sodium chloride. Prolonged absorption of the injectable compositions can be brought about by the use in the compositions of agents delaying absorption, for example, aluminum monostearate and gelatin.

[0162] Sterile injectable solutions are prepared by incorporating the active compounds in the required amount in the appropriate solvent with various other ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the various sterilized active ingredients into a sterile vehicle which contains the basic dispersion medium and the required other ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, the preferred methods of preparation are vacuum-drying and freeze-drying techniques which yield a powder of the active ingredient plus any additional desired ingredient from a previously sterile-filtered solution thereof.

Therapeutic agents

[0163] In certain embodiments, therapeutic agents may be attached to a targeting peptide or fusion protein for selective delivery to, for example, white adipose tissue.

Agents or factors suitable for use may include any chemical compound that induces apoptosis, cell death, cell stasis and/or anti-angiogenesis.

Regulators of Programmed Cell Death

[0164] Apoptosis, or programmed cell death, is an essential process for normal embryonic development, maintaining homeostasis in adult tissues, and suppressing carcinogenesis (Kerr *et al.*, 1972). The Bcl-2 family of proteins and ICE-like proteases have been demonstrated to be important regulators and effectors of apoptosis in other systems. The Bcl-2 protein, discovered in association with follicular lymphoma, plays a prominent role in controlling apoptosis and enhancing cell survival in response to diverse apoptotic stimuli (Bakhshi *et al.*, 1985; Cleary and Sklar, 1985; Cleary *et al.*, 1986; Tsujimoto *et al.*, 1985; Tsujimoto and Croce, 1986). The evolutionarily conserved Bcl-2 protein now is recognized to be a member of a family of related proteins, which can be categorized as death agonists or death antagonists.

[0165] Subsequent to its discovery, it was shown that Bcl-2 acts to suppress cell death triggered by a variety of stimuli. Also, it now is apparent that there is a family of Bcl-2 cell death regulatory proteins that share in common structural and sequence homologies. These different family members have been shown to either possess similar functions to Bcl-2 (e.g., Bcl_{XL}, Bcl_w, Bcl_s, Mcl-1, A1, Bfl-1) or counteract Bcl-2 function and promote cell death (e.g., Bax, Bak, Bik, Bim, Bid, Bad, Harakiri).

[0166] Non-limiting examples of pro-apoptosis agents contemplated within the scope of the present invention include gramicidin, magainin, mellitin, defensin, cecropin, (KLAKLAK)₂ (SEQ ID NO:1), (KLAKKLA)₂ (SEQ ID NO:2), (KAAKKAA)₂ (SEQ ID NO:3) or (KLGKKLG)₃ (SEQ ID NO:4).

Angiogenic inhibitors

[0167] In certain embodiments the present invention may concern administration of targeting peptides attached to anti-angiogenic agents, such as angiotensin, laminin peptides, fibronectin peptides, plasminogen activator inhibitors, tissue metalloproteinase inhibitors, interferons, interleukin 12, platelet factor 4, IP-10, Gro- β , thrombospondin, 2-methoxyoestradiol, proliferin-related protein, carboxyamidotriazole, CM101, Marimastat, pentosan polysulphate, angiopoietin 2 (Regeneron), interferon-alpha, herbimycin A,

PNU145156E, 16K prolactin fragment, Linomide, thalidomide, pentoxifylline, genistein, TNP-470, endostatin, paclitaxel, accutin, angiostatin, cidofovir, vincristine, bleomycin, AGM-1470, platelet factor 4 or minocycline.

Proliferation of tumors cells relies heavily on extensive tumor vascularization, which accompanies cancer progression. Thus, inhibition of new blood vessel formation with anti-angiogenic agents and targeted destruction of existing blood vessels have been introduced as an effective and relatively non-toxic approach to tumor treatment. (Arap *et al.*, *Science* 279:377-380, 1998; Arap *et al.*, *Curr. Opin. Oncol.* 10:560-565, 1998; Ellerby *et al.*, *Nature Med.* 5:1032-1038, 1999). A variety of anti-angiogenic agents and/or blood vessel inhibitors are known. (E.g., Folkman, In: *Cancer: Principles and Practice*, eds. DeVita *et al.*, pp. 3075-3085, Lippincott-Raven, New York, 1997; Eliceiri and Chersesh, *Curr. Opin. Cell. Biol.* 13, 563-568, 2001).

White fat represents a unique tissue that, like tumors, can quickly proliferate and expand (Wasserman, In: *Handbook of Physiology*, eds. Renold and Cahill, pp. 87-100, American Physiological Society, Washington, D.C., 1965; Cinti, *Eat. Weight. Disord.* 5:132-142, 2000). Studies of adipose tissue reveal that it is highly vascularized. Multiple capillaries make contacts with every adipocyte, suggesting the importance of the vasculature for maintenance of the fat mass (Crandall *et al.*, *Microcirculation* 4:211-232, 1997). A hypothesis underlying the present invention is that adipose tissue proliferation might rely on angiogenesis similarly to tumors. If so, destruction of fat neovasculature could prevent the development of obesity, whereas targeting existing adipose blood vessels could potentially result in fat regression. Methods of use of adipose targeting peptides may include induction of weight loss, treatment of obesity and/or treatment of HIV related lipodystrophy.

Cytotoxic Agents

[0168] Chemotherapeutic (cytotoxic) agents of potential use include, but are not limited to, 5-fluorouracil, bleomycin, busulfan, camptothecin, carboplatin, chlorambucil, cisplatin (CDDP), cyclophosphamide, dactinomycin, daunorubicin, doxorubicin, estrogen receptor binding agents, etoposide (VP16), farnesyl-protein transferase inhibitors, gemcitabine, ifosfamide, mechlorethamine, melphalan, mitomycin, navelbine, nitrosurea, plicomycin, procarbazine, raloxifene, tamoxifen, taxol, temazolomide (an

aqueous form of DTIC), transplatinum, vinblastine and methotrexate, vincristine, or any analog or derivative variant of the foregoing. Most chemotherapeutic agents fall into the categories of alkylating agents, antimetabolites, antitumor antibiotics, corticosteroid hormones, mitotic inhibitors, and nitrosoureas, hormone agents, miscellaneous agents, and any analog or derivative variant thereof.

[0169] Chemotherapeutic agents and methods of administration, dosages, etc. are well known to those of skill in the art (see for example, the "Physicians Desk Reference", Goodman & Gilman's "The Pharmacological Basis of Therapeutics" and in "Remington's Pharmaceutical Sciences" 15th ed., pp 1035-1038 and 1570-1580, incorporated herein by reference in relevant parts), and may be combined with the invention in light of the disclosures herein. Some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person responsible for administration will, in any event, determine the appropriate dose for the individual subject. Examples of specific chemotherapeutic agents and dose regimes are also described herein. Of course, all of these dosages and agents described herein are exemplary rather than limiting, and other doses or agents may be used by a skilled artisan for a specific patient or application. Any dosage in-between these points, or range derivable therein is also expected to be of use in the invention.

Alkylating agents

[0170] Alkylating agents are drugs that directly interact with genomic DNA to prevent cells from proliferating. This category of chemotherapeutic drugs represents agents that affect all phases of the cell cycle, that is, they are not phase-specific. An alkylating agent, may include, but is not limited to, a nitrogen mustard, an ethylenimine, a methylmelamine, an alkyl sulfonate, a nitrosourea or a triazines. They include but are not limited to: busulfan, chlorambucil, cisplatin, cyclophosphamide (cytoxan), dacarbazine, ifosfamide, mechlorethamine (mustargen), and melphalan.

Antimetabolites

[0171] Antimetabolites disrupt DNA and RNA synthesis. Unlike alkylating agents, they specifically influence the cell cycle during S phase. Antimetabolites can be differentiated into various categories, such as folic acid analogs, pyrimidine analogs and purine analogs and related inhibitory compounds. Antimetabolites include but are not

limited to, 5-fluorouracil (5-FU), cytarabine (Ara-C), fludarabine, gemcitabine, and methotrexate.

Natural Products

[0172] Natural products generally refer to compounds originally isolated from a natural source, and identified as having a pharmacological activity. Such compounds, analogs and derivatives thereof may be, isolated from a natural source, chemically synthesized or recombinantly produced by any technique known to those of skill in the art. Natural products include such categories as mitotic inhibitors, antitumor antibiotics, enzymes and biological response modifiers.

[0173] Mitotic inhibitors include plant alkaloids and other natural agents that can inhibit either protein synthesis required for cell division or mitosis. They operate during a specific phase during the cell cycle. Mitotic inhibitors include, for example, docetaxel, etoposide (VP16), teniposide, paclitaxel, taxol, vinblastine, vincristine, and vinorelbine.

[0174] Taxoids are a class of related compounds isolated from the bark of the ash tree, *Taxus brevifolia*. Taxoids include but are not limited to compounds such as docetaxel and paclitaxel. Paclitaxel binds to tubulin (at a site distinct from that used by the vinca alkaloids) and promotes the assembly of microtubules.

[0175] Vinca alkaloids are a type of plant alkaloid identified to have pharmaceutical activity. They include such compounds as vinblastine (VLB) and vincristine.

Antibiotics

[0176] Certain antibiotics have both antimicrobial and cytotoxic activity. These drugs also interfere with DNA by chemically inhibiting enzymes and mitosis or altering cellular membranes. These agents are not phase specific so they work in all phases of the cell cycle. Examples of cytotoxic antibiotics include, but are not limited to, bleomycin, dactinomycin, daunorubicin, doxorubicin (Adriamycin), plicamycin (mithramycin) and idarubicin.

Miscellaneous Agents

[0177] Miscellaneous cytotoxic agents that do not fall into the previous categories include, but are not limited to, platinum coordination complexes, anthracenediones,

substituted ureas, methyl hydrazine derivatives, amsacrine, L-asparaginase, and tretinoin. Platinum coordination complexes include such compounds as carboplatin and cisplatin (*cis*-DDP). An exemplary anthracenedione is mitoxantrone. An exemplary substituted urea is hydroxyurea. An exemplary methyl hydrazine derivative is procarbazine (N-methylhydrazine, MIII). These examples are not limiting and it is contemplated that any known cytotoxic, cytostatic or cytocidal agent may be attached to targeting peptides and administered to a targeted organ, tissue or cell type within the scope of the invention.

Dosages

[0178] The skilled artisan is directed to "Remington's Pharmaceutical Sciences" 15th Edition, chapter 33, and in particular to pages 624-652. Some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person responsible for administration will, in any event, determine the appropriate dose for the individual subject. Moreover, for human administration, preparations should meet sterility, pyrogenicity, and general safety and purity standards as required by the FDA Office of Biologics standards.

EXAMPLES

[0179] The following examples are included to demonstrate preferred embodiments of the invention. It should be appreciated by those of skill in the art that the techniques disclosed in the examples which follow represent techniques discovered by the inventors to function well in the practice of the invention, and thus can be considered to constitute preferred modes for its practice. However, those of skill in the art should, in light of the present disclosure, appreciate that many changes can be made in the specific embodiments which are disclosed and still obtain a like or similar result without departing from the spirit and scope of the invention.

Example 1. Identification of mouse placenta targeting peptides

Identification of placenta homing peptides

[0180] Peptides homing to the mouse placenta were identified by a post-clearing protocol using a phage display library. A first round of biopanning was performed on pregnant mice. Samples of placenta were removed and phage rescued according to protocols described below, with one modification. In the typical biopanning protocol,

thousands of phage may be recovered from a single organ, tissue or cell type. Typically, between 200 and 300 individual colonies are selected from plated phage and these are amplified and pooled to form the phage display library for the second or third rounds of biopanning. In the present Example, all phage rescued from the first round of biopanning were amplified in bulk on solid medium and then pooled to form the phage display library for the second round of biopanning. That is, there was no restriction of the rescued phage from the first round of biopanning. This *in vivo* biopanning without restriction was performed for three rounds (rounds I-III), then a post-clearing procedure was used.

[0181] In a post-clearing protocol (round IV), phage were administered to a non-pregnant mouse. Phage that bound to tissues other than placenta were absorbed from the circulation. Remaining phage were recovered from the plasma of the non-pregnant mouse. This protocol was designed to isolate phage that bound to placenta but not to other mouse organs, tissues or cell types. The following placenta-targeting peptides were identified, along with their frequencies. A search of the GenBank database disclosed that none of the sequences listed below was 100% homologous with any known peptide sequence.

TPKTSVT (SEQ ID NO:5) 7.4% in round III, 8.5% in round IV

RMDGPVR (SEQ ID NO:6) 3.1% in round III, 8.5% in round IV

RAPGGVR (SEQ ID NO:7) <1% in round III, 8.5% in round IV

VGLHARA (SEQ ID NO:8) 4.2% in round III, 7.4% in round IV

YIRPFTL (SEQ ID NO:9) 2.1% in round III, 5.3% in round IV

LGRLSVG (SEQ ID NO:10) <1% in round III, 5.3% in round IV

PSERSPS (SEQ ID NO:11) (data not available)

[0182] As can be seen, the use of a post-clearing procedure resulted in a substantial enrichment of phage bearing placenta targeting peptides. Although this procedure was used for placenta, the skilled artisan will realize that post-clearance can be performed for any organ, tissue or cell type where a phage library can be administered to a subject lacking that organ, tissue or cell type. For example, a post-clearing procedure for

prostate or testicle targeting peptides could be performed in a female subject, and for ovary, vagina or uterus in a male subject.

[0183] A homology search identified several candidate proteins as endogenous analogs of the placental targeting peptides, including TCR gamma-1 (TPKTSVT, SEQ ID NO:5), tenascin (RMDGPVR, SEQ ID NO:6 and RAPGGVR, SEQ ID NO:7), angiotensin I (YIRPFTL, SEQ ID NO:9) and MHC H2-D-q alpha chain (VGLHARA, SEQ ID NO:8).

Validation of placenta homing peptides and inhibition of pregnancy

[0184] The placenta homing peptides were validated *in vivo* by injection into pregnant mice and recovery from the placenta. FIG. 1 shows the results of the validation studies for selected placenta homing phage. The phage clones are identified as: PA - TPKTSVT (SEQ ID NO:5), PC - RAPGGVR (SEQ ID NO:7), PE - LGLRSVG (SEQ ID NO:10), PF - YIRPFTL (SEQ ID NO:9). It can be seen that the PA clone exhibited placental homing more than an order of magnitude greater than observed with control fd-tet phage. The PC clone also showed substantially higher placental localization, while the PE and PF clones were not substantially enriched in placenta compared to control phage.

[0185] Despite the absence of apparent enrichment of the PF clone in placental tissue, both the PA and PF peptides showed anti-placental activity. Table 3 shows the effects of the PA and PF placental targeting peptides injected into pregnant mice, attached to FITC (fluorescein isothiocyanate), GST (glutathion S-transferase) or to phage. At lower dosages (450 µg total), FITC conjugated PA and PF showed a slight effect on pregnancy (Table 3). At higher dosages (800 to 1000 µg protein or 4.5×10^{10} phage), both protein and phage conjugated PA and PF peptides substantially interfered with fetal development (Table 3), apparently resulting in death of the fetuses in most cases. The CARAC peptide (SEQ ID NO:12), an adipose targeting peptide (FE, TREVHRS, SEQ ID NO:13) or fd-tet phage were used as non-placental targeting controls.

Table 3. Effect of Placental Targeting Peptides on Fetal Development**Inhibition with FITC conjugates -I**

1 mouse injected iv (predominantly) or ip -every other day, day 1-day 18,
9 times, Total 450 mM (~450 μ g)

Peptide Injected	Pregnancy Outcome	Peptide Effect on Embryo
CARAC-FITC (- control)	Delivery: 18d, 5 normal pups	No effect
PA-FITC (placenta homer)	Delivery: 19d, 8 normal pups	No effect
PF-FITC (placenta homer)	Delivery: 21d, 1 dead pup	Development delay, toxicity

Inhibition with FITC conjugates -II

1 mouse injected sc (predominantly) or iv -every other day, day 4-day 17,
10 times, Total 1 M (~1mg)

Peptide Injected	Pregnancy Outcome	Peptide Effect on Embryo
CARAC-FITC (- control)	Delivery: 20d, 5 pups, 1-dead	Slight toxicity?
PA-FITC (placenta homer)	No fetuses inside after 21 d	Pregnancy termination
PF-FITC (placenta homer)	No fetuses inside after 21 d	Pregnancy termination

Inhibition with phage conjugates -I

1 mouse injected iv (predominantly) or ip -every other day, day 1-day 18,
9 times, Total 4.5x10¹⁰ TU

Peptide Injected	Pregnancy Outcome	Peptide Effect on Embryo
Fd-Tet (- control)	Avertin OD=>death. fetuses-OK	?
PA-phage (placenta homer)	Delivery: 24d, 4 pups, 1-dead	Development delay, i
PF-phage (placenta homer)	Delivery: 25d, 8 pups, all dead	Development delay, toxicity

Inhibition with GST conjugates -I
--

1 mouse injected sc (predominantly) or iv ~every other day, day 4-day 17,
10 times, Total 800 μ g

Peptide Injected	Pregnancy Outcome	Peptide Effect on Embryo
GST-FE (- control)	Delivery: 20d, 2 pups, OK	No effect
GST-PA (placenta homer)	No delivery or fetuses after 21 d	Pregnancy termination
GST-PF (placenta homer)	Day 15: no fetuses inside, uterus necrotic	Pregnancy termination

[0186] These results validate the placental targeting peptide sequences identified above. They further demonstrate that even in the absence of substantial enrichment of phage bearing the targeting sequence to the target organ (e.g. peptide PF, FIG. 1), the targeting peptide may nevertheless provide for targeted delivery of therapeutic agents to the target organ. In this study, it appeared that at lower dosages the PF peptide was more effective than the PA peptide at interfering with pregnancy, despite the observation that the PA peptide produced a many-fold higher level of phage localization to placenta.

[0187] The skilled artisan will realize that the disclosed methods and peptides may be of use for targeted delivery of therapeutic agents to the fetus through the placenta, as well as for novel approaches to terminating pregnancy and/or inducing labor.

Example 2. Localization of the TPKTSVT (SEQ ID NO:5) Peptide in Mouse Placenta

Material and Methods

Animals Staged pregnant 18 days postconception (dpc) C57BL/6 female mice were purchased from Harlan Teklad (Indianapolis, IN). Congenic pregnant β 2m-null females (stock 002087) mice were purchased from The Jackson Laboratories (Bar Harbor, ME). Anesthesia was performed with Avertin (0.015 ml/g) administered intraperitoneally (Pasqualini and Ruoslahti, 1996, *Nature* **380**:364-366; Rajotte *et al.*, 1998, *J. Clin. Invest.* **102**: 430-437).

Phage Library Screening *In vivo* screening of an M13 page-display CX₇C library (Pasqualini *et al.*, 2000, in *Phage Display: A Laboratory Manual*, eds. Barbas *et al.*,

Cold Spring Harbor Laboratory Press, New York, NY, pp. 22.1-24; Arap *et al.*, 2002, *Nature Med.* 8:121-127), for placenta-homing peptides was performed as described (Pasqualini *et al.*, 2000; Pasqualini and Ruoslahti, 1996) with novel modifications described below. In each biopanning round, an 18 dpc C57BL/6 female was injected intravenously (tail vein) with 10^{10} transducing units (TU) of the library. Increasing amounts of phage (from $\sim 10^3$ TU in round 1 to $\sim 10^4$ TU in round 4) were recovered from the placentas after 5 min of circulation. Recovered phage were bulk-amplified for subsequent rounds of screening. In a procedure introduced here for the first time, the sub-library that was amplified after the third round of panning was cleared of nonspecific binders in a subtraction step. A virgin C57BL/6 female was infused through the tail vein with 10^9 TU of phage selected in round 3. After 5 min, the unbound circulating phage were recovered from plasma. The plasma contained approximately 10^7 TU of pre-cleared phage. The pre-cleared phage population, representing less than 1% of the injected pool, was recovered and amplified for the final round of biopanning.

Phage Recovery Mouse placentas and embryonic livers were individually weighed, ground with a glass Dounce homogenizer and suspended in 1 ml of Dulbecco's Modified Eagle's Medium (DMEM) containing proteinase inhibitors (DMEM-prin - 1 mM PMSF, 20 μ g/ml aprotinin, and 1 μ g/ml leupeptin). The suspension was vortexed and washed three times with DMEM-prin. Tissue homogenates (or 10 ml of blood for normalization of phage titer in placenta against circulating phage titer) were incubated with 1 ml of host bacteria (log phase *E. coli* K91kan; OD600 ~ 2). Aliquots of the bacterial culture were plated onto Luria-Bertani agar plates containing 40 μ g/ml tetracycline and 100 μ g/ml kanamycin. Plates were incubated overnight at 37°C. Triplicate samples were processed for host bacterial infection, phage recovery, and histological analysis.

Fusion and Recombinant Peptides Carboxyfluorescein (FITC)-conjugated CTPKTSVTC (SEQ ID NO:144) or control peptide CARAC (SEQ ID NO:12), formed into cyclic peptides using the flanking cysteines, were chemically synthesized and HPLC-purified to >90% purity by Anaspec (San Jose, CA). The FITC-peptide stocks were made by dissolving lyophilized peptides in DMSO to a concentration of 20 mM, after which the peptides were diluted to 1 mM with PBS (phosphate buffered saline) and

aliquots were frozen until use. The CTPKTSVTC (SEQ ID NO:144) peptide and an unrelated control peptide, CTREVHRSC (SEQ ID NO:87), fused in-frame with GST at the amino-terminus were purified to approximately 90% purity using the BugBuster GST Bind Kit (Novagen, Madison, WI). Purified peptides were buffer-exchanged into PBS using Centricon PL-10 columns (Millipore, Bedford, MA) and the aliquots were frozen until use. For *in vivo* peptide homing validation, 10 μ l of FITC-peptide stocks diluted 20-fold with PBS or 250 μ l of 5 mg/ml GST-peptides were injected. For phage homing competition and IgG transcytosis blocking experiments, 500 μ l of 5 mg/ml GST-peptides were administered intravenously.

Peptide Localization in Tissues Immunohistochemistry on sections of formalin-fixed, paraffin-embedded mouse tissue was performed as described (Pasqualini *et al.*, 2000; Pasqualini and Ruoslahti, 1996). For phage-peptide immunolocalization, a rabbit anti- ϕ d phage antibody (Sigma Chemicals, St. Louis, MO) was used at 1:1,000 dilution and detected with a secondary horseradish peroxidase (HRP)-conjugated antibody. For GST-peptide immunolocalization, a goat anti-GST antibody (Amersham, Piscataway, NJ) was used at 1:1,000 dilution and detected with a secondary alkaline phosphatase (AP)-conjugated antibody. For mouse IgG immunolocalization, the ARK Peroxidase Kit (DAKO, Carpinteria, CA) was used. All immunohistochemistry and FITC immunofluorescence images were captured using an Olympus IX70 microscope and digital camera setup.

Peptide Embryotoxicity For peptide embryotoxicity studies, agents were injected at the following daily doses: GST-peptides 0.1 mg (~3 nMoles), FITC-peptides 50 μ g (~30 nMoles), and phage-peptides 10^{11} TU. All agents were dissolved in PBS. Mice were injected subcutaneously in the back (5-10 injections per course).

Results

Localization of the TPKTSVT (SEQ ID NO:5) Peptide in Mouse Placenta The tissue distribution of recombinant phage injected into pregnant mice was examined by immunohistochemistry (FIG. 3). While a control phage barely localized to placental tissues (FIG. 3A), the TPKTSVT (SEQ ID NO:5) phage homed to the placenta and showed marked localization to the villi of the visceral yolk sac (vys) endoderm (FIG. 3B, arrows). The vys is a layer of epithelial cells which surrounds the embryonic

microvasculature and functions as the final barrier during transport of molecules, such as immunoglobulin G (IgG), from the labyrinth layer of the placenta into the fetus (Rugh, 1990; Beckman *et al.*, 1990; Lyden *et al.*, 2001, *J. Immunol.* 166:3882-3889; Jollie, 1990, *Teratology* 41:361-381).

To verify that targeting of the TPKTSVT (SEQ ID NO:5) motif to the vys endoderm also occurs if the peptide is outside of the context of the phage, the homing of TPKTSVT (SEQ ID NO:5) fused with glutathione S-transferase (GST) protein to placenta was also tested. GST fused to either TPKTSVT (SEQ ID NO:5) or a control peptide TREVHRS (SEQ ID NO:13) with a similar overall charge were injected into pregnant mice and the tissue distribution of each peptide was examined. No localization of the control GST fusion peptide to the placenta was observed (FIG. 3C). In contrast, accumulation of the TPKTSVT (SEQ ID NO:5) GST fusion peptide was readily detectable in the apical cytoplasm of the vys (FIG. 3D, arrows) and matched that observed for TPKTSVT (SEQ ID NO:5)-phage (FIG. 3B, arrows).

Similarly, fluorescein (FITC)-conjugated TPKTSVT (SEQ ID NO:5) injected intravenously into pregnant mice also specifically localized to the apical vys cytoplasm (FIG. 3F). A control peptide FITC conjugate was not detectable in the placenta (FIG. 3E). Localization of TPKTSVT (SEQ ID NO:5)-phage, TPKTSVT (SEQ ID NO:5)-GST, or TPKTSVT (SEQ ID NO:5)-FITC to control organs, such as brain and pancreas, was not detected (data not shown). Together, these data show that the TPKTSVT (SEQ ID NO:5) peptide targets the placenta, with the strongest homing noticed in the vys (FIG. 3B, FIG. 3D and FIG. 3F).

The TPKTSVT (SEQ ID NO:5) Peptide Binds to a Placental Transporter The TPKTSVT (SEQ ID NO:5) peptide localizes to the vys (FIG. 3), which is the tissue primarily responsible for materno-fetal transport in mice. This motif was tested to see if it would promote phage transport into the embryo. Either TPKTSVT (SEQ ID NO:5)-phage or control phage were injected into pregnant mice and the recovery of phage from embryos was determined. Specific accumulation of TPKTSVT (SEQ ID NO:5)-phage in embryos was observed to be up to 1,000-fold greater than that of control phage (FIG. 4A). The TPKTSVT (SEQ ID NO:5) peptide was observed to apparently bind to a specific placental transporter. The materno-fetal transfer of TPKTSVT (SEQ ID NO:5)-

phage was blocked by an excess of co-injected TPKTSVT (SEQ ID NO:5) peptide, but not the control GST fusion peptide (FIG. 4A), suggesting transport by a specific receptor protein as opposed to non-specific uptake.

Phage immunocytochemistry confirmed that the uptake of TPKTSVT (SEQ ID NO:5)-phage by the vys cells was not affected by the control GST fusion peptide (FIG. 4A, FIG. 4B and FIG. 4C). FIG. 4B shows that TPKTSVT (SEQ ID NO:5)-phage administered alone are localized to the vys (arrows). FIG. 4C shows that in the presence of control-GST fusion peptides, the TPKTSVT (SEQ ID NO:5)-phage still localize to the vys (arrows). In contrast, the addition of TPKTSVT (SEQ ID NO:5)-GST fusion peptide prevented internalization of TPKTSVT (SEQ ID NO:5)-phage into the vys epithelium (FIG. 4D). Together, these results show that the TPKTSVT (SEQ ID NO:5) peptide is actively transported through the placenta into the embryo by binding to a receptor located on endothelial cells in the vys.

The TPKTSVT (SEQ ID NO:5) Peptide Blocks Placental IgG Transport The pattern of the TPKTSVT (SEQ ID NO:5) localization to the placenta (FIG. 3) is reminiscent of that observed for IgG in that tissue (Parr and Parr, 1985, *J. Reprod. Immunol.* 8: 153-171). Moreover, both IgG and TPKTSVT (SEQ ID NO:5) appear to undergo a receptor-mediated transport into the embryo during pregnancy. It was hypothesized that IgG and TPKTSVT (SEQ ID NO:5) bind to a common receptor in the placenta. The results presented herein show that the TPKTSVT (SEQ ID NO:5) peptide competes for the placental transport of IgG.

Intravenous administration of a control GST-fusion peptide did not affect the placental transfer of IgG to the vys (FIG. 5A, arrowheads). In contrast, co-administration of an equimolar dose of TPKTSVT (SEQ ID NO:5)-GST blocked translocation of IgG through the placenta (FIG. 5B). Although IgG localization to the labyrinthine blood vessels in the embryo-distal placental compartments was still detectable (FIG. 5B, asterisks), IgG staining in the vys epithelium was markedly decreased (FIG. 5B). The vys levels of IgG in the presence of TPKTSVT (SEQ ID NO:5)-GST were similar to those observed in β_{2m} -null mice (not shown), which are genetically deficient in IgG transcytosis (Israel *et al.*, 1995, *J. Immunol.* 154:6246-6251; Zijlstra, *et al.*, 1990, *Nature* 344:742-746). Based on these data, it is proposed that the

TPKTSVT (SEQ ID NO:5) peptide selectively blocks transport through an immunoglobulin Fc receptor that mediates the uptake of IgG by the yolk sac (FIG. 5C and FIG. 5D).

The TPKTSVT (SEQ ID NO:5) Receptor is Associated with the β_2m Protein

FcRn is a β_2m -associated Class I major histocompatibility complex (MHC-I) homologue. FcRn appears to regulate placental IgG transport (Ghetie and Ward, 2000, *Ann. Rev. Immunol.* 18:739-766; Simister and Story, 1997, *J. Reprod. Immunol.* 37:1-23). This is supported by the observation that IgG species which are incapable of binding to FcRn are not transported across the human placenta in an *ex vivo* model (Firan *et al.*, 2001, *Int. Immunol.* 13:993-1002). In addition, FcRn expression patterns in the placenta resemble the pattern of placental IgG localization (Saji *et al.*, 1999, *Rev. Reprod.* 4:81-89). A search of the mouse protein database using BLAST software (NCBI; <http://www.ncbi.nlm.nih.gov/BLAST/>) revealed the similarity of the TPKTSVT (SEQ ID NO: 5) placental targeting peptide to the sequence PPKTTVT (amino acids 192-198 of the mouse MHC-I; Genbank accession AAD43175). Moreover, the corresponding conserved human MHC-I sequence, PPKTHVT, is exposed on the surface of the MHC-I α_3 chain immediately adjacent to H-192 residue, a known β_2m contact site in the α_3 domain of MHC-I homologues (Tysoe-Calnon *et al.*, 1991, *Biochem. J.* 277:359-369). This makes the TPKTSVT (SEQ ID NO:5) motif an apparent mimeotope of FcRn. Homing of the TPKTSVT (SEQ ID NO:5) peptide to the placenta, despite expression of FcRn in other tissues, may be due to either differential association of additional receptor subunits, or by altered accessibility of the receptor to the circulating ligand in the placenta. This is consistent with previous reports of FcRn interacting with IgG in the placenta through a mechanism different from that in other tissues (Ghetie and Ward, *Ann. Rev. Immunol.* 18:739-766, 2000; Simister and Story, *J. Reprod. Immunol.* 37:1-23, 1997).

The TPKTSVT (SEQ ID NO: 5) motif was tested to determine if it targets the FcRn/ β_2m receptor complex in the placenta. The β_2m -deficient mouse strain, in which FcRn is not functional (Isreal *et al.*, 1995, *J. Immunol.* 154:6246-51; Zijlstra *et al.*, 1990, *Nature* 344:742-746), was used as a model system to test whether the TPKTSVT (SEQ ID NO:5) peptide is a ligand for the FcRn/ β_2m receptor complex. Phage displaying the

TPKTSVT (SEQ ID NO:5) peptide were intravenously injected into pregnant β_2m -null mice and the recovery of phage from the placenta was assayed (FIG. 6). While the TPKTSVT (SEQ ID NO:5)-phage (FIG. 6A, white bars) homed to the wild-type (+/+) placenta relative to control phage (FIG. 6A, black bars), no such homing was detectable in β_2m -deficient mice (FIG. 6A). Immunohistochemical analysis of phage accumulation in β_2m wild-type (FIG. 3B) and β_2m -null (FIG. 6B) placentas confirmed that TPKTSVT (SEQ ID NO:5)-phage were not taken up by the vys epithelium in the β_2m -deficient mice. In contrast, *in vivo* localization of a control phage displaying a different placenta homing peptide, YIRPFTL (SEQ ID NO:9), which, unlike TPKTSVT (SEQ ID NO:5) peptide, homes to the vasculature of the labyrinthine placenta, rather than to the vys, was not affected in β_2m -null mice (FIG. 6C, arrowheads). Together, these observations strongly suggest that the TPKTSVT (SEQ ID NO:5) motif targets the placenta by binding to FcRn/ β_2m .

The TPKTSVT (SEQ ID NO: 5) Peptide Interferes with Mouse Pregnancy

Because FcRn/ β_2m regulates materno-fetal exchange, the above observations suggested that TPKTSVT (SEQ ID NO:5) might interfere with placental transport and embryonic development. TPKTSVT (SEQ ID NO:5) peptide was administered to pregnant mice in three different forms - displayed on the phage capsid, fused to GST or fused to FITC. The phage or fusion peptides were subcutaneously injected and the progression of pregnancy was compared with mice injected with control phage, control peptides, or saline. Multiple injections of the TPKTSVT (SEQ ID NO:5) peptide were administered, starting at mid-pregnancy (~12 days postconception, dpc) in doses non-toxic to the mother.

The effect of TPKTSVT (SEQ ID NO:5) peptide on fetal development is illustrated in FIG. 7A and FIG. 7B. TPKTSVT (SEQ ID NO:5) peptide inhibited the progression of pregnancy, as evidenced by diminished weight gain in mice injected with the TPKTSVT (SEQ ID NO:5) phage or GST fusion peptide compared to control phage or GST-peptide (FIG. 7A). The course of pregnancy courses in mice injected with control peptides were undistinguishable from those in saline-injected mice (data not shown).

Examination of embryos on the 20th day of pregnancy (the delivery day for the control) revealed that the TPKTSVT (SEQ ID NO:5) peptide has a severe effect on embryonic development. Growth-retarded, dead, or partially resorbed embryos were observed in mice injected with either TPKTSVT (SEQ ID NO:5)-phage, TPKTSVT (SEQ ID NO:5)-GST, or TPKTSVT (SEQ ID NO:5)-FITC (FIG. 7B, embryo to right of figure). The normal development of a mouse embryo injected with control peptide is shown on the left side of FIG. 7B. Administration of TPKTSVT (SEQ ID NO:5) fusion peptides to pregnant mice resulted in 43% complete embryo resorption and 21% dead or malformed conceptuses (FIG. 7B). The extent of embryo resorption and frequency of complete pregnancy abortion increased with prolonged TPKTSVT (SEQ ID NO:5) treatment (data not shown), suggesting that the peptide effect is dose-dependent. Embryo death or morbidity were not observed in any of the control groups.

Morphologic inspection of tissues from TPKTSVT (SEQ ID NO:5) peptide-injected mice revealed that, in contrast to controls, placentas were edematous and grossly deformed. Histopathological examination of the placentas showed that the TPKTSVT (SEQ ID NO:5) treatment induced massive dilation of blood vessels and intraplacental bleeding, as well as widespread hemorrhagic necrosis (FIG. 7D). Hematoxylin staining of the placental epithelium after seven days of peptide administration showed that most nuclei in the yolk sac and many in the labyrinthine compartment were degraded (FIG. 7D). Also, massive fibrosis was evident in the yolk sac cavity and in the labyrinthine portion of the placenta (FIG. 7D). In contrast, placentas from mice injected with control peptides (FIG. 7C) were indistinguishable from untreated placentas at corresponding stages of pregnancy. The effect of TPKTSVT (SEQ ID NO:5) peptide on the reproductive system was strikingly specific, as histological examination of control organs revealed no pathological changes or necrosis, and no signs of peptide toxicity to the mother were observed (data not shown).

The teratogenicity observed with TPKTSVT (SEQ ID NO:5) is probably not caused by the disruption of the $\text{FcRn}/\beta_2\text{M}$ receptor function, as the fertility of mice is not significantly affected by $\beta_2\text{M}$ deficiency (Zijlstra *et al.*, *Nature* 344:742-46, 1990). Rather, embryotoxicity is likely secondary to placental thrombosis and ischemia. An

alternative mechanism could be activation of complement and an immune response against the targeting peptide itself.

These results have important implications for the development of pregnancy-safe therapeutics, as it appears that a substance can cause embryotoxicity by merely homing to a placental cell surface marker without inactivating the receptor function. This creates the basis for a high throughput identification system based on placental receptors prone to teratogen binding. Systematic screening of potential teratogens for binding to such receptors could be used to identify teratogenic activity and decrease the risk of teratogen induced birth defects.

Example 3. Identification of mouse adipose targeting peptides

Adipose targeting peptides

[0188] A similar protocol to that disclosed in Example 1 was used to isolate fat targeting peptides from a genetically obese mouse (Zhang *et al.*, *Nature*, 372:425-432, 1994; Pelleymounter *et al.*, *Science* 269:540-543, 1995). Phage that had been subjected to biopanning in obese mice were post-cleared in a normal mouse. The fat-targeting peptides isolated included TRNTGNI (SEQ ID NO:14), FDGQDRS (SEQ ID NO:15); WGPKRL (SEQ ID NO:16); WGESRL (SEQ ID NO:17); VMGSVTG (SEQ ID NO:18); KGGRAKD (SEQ ID NO:19), RGEVLWS (SEQ ID NO:20), TREVHRS (SEQ ID NO:13) and HGQGVPR (SEQ ID NO:21).

[0189] Homology searches identified several candidate proteins as the endogenous analogs of the fat targeting peptides, including stem cell growth factor (SCGF) (KGGRAKD, SEQ ID NO:19), attractin (mahogany) (RGEVLWS, SEQ ID NO:20), angiopoietin-related adipose factor (FIAF) (TREVHRS, SEQ ID NO:13), adipophilin (ADRP) (VMGSVTG, SEQ ID NO:18), Flt-1 or procollagen type XVII (TRNTGNI, SEQ ID NO:14) and fibrillin 2 or transferrin-like protein p97 (HGQGVPR, SEQ ID NO:21)

Validation of adipose targeting peptides

[0190] The fat homing peptides were validated by *in vivo* homing, as shown in FIG. 2. The fat homing clones selected were: FA - KGGRAKD (SEQ ID NO:19), FC - RGEVLWS (SEQ ID NO:20), FE - TREVHRS (SEQ ID NO:13) and FX - VMGSVTG

(SEQ ID NO:18). As seen in FIG. 2, all of these clones exhibited some elevation of homing to adipose tissue, with clone FX showing several orders of magnitude higher adipose localization than control fd-tet phage. Clone FX also exhibited substantially higher localization than the other selected fat homing clones. However, by analogy with the placental homing peptides disclosed above, the skilled artisan will realize that fat homing clones exhibiting lower levels of adipose tissue localization may still be of use for targeted delivery of therapeutic agents.

[0191] The skilled artisan will realize that targeting peptides selective for angiogenic vasculature in adipose tissue could be of use for weight reduction or for preventing weight gain. By attaching anti-angiogenic or toxic moieties to an adipose targeting peptide, the blood vessels supplying new fat tissue could be selectively inhibited, preventing the growth of new deposits of fat and potentially killing existing fat deposits.

Example 4: CKGGRAKDC (SEQ ID NO: 22) homes to white fat in ob/ob mice

Materials and Methods

Experimental animals

C57BL/6 mice were purchased from Harlan Teklad. Leptin-deficient (ob/ob) (stock 000632) and leptin receptor-deficient (stock 000642) mice were purchased from Jackson Laboratories (Bar Harbor, ME). Anesthesia was performed with Avertin (0.015 ml/g) administered intraperitoneally (Arap, *et al.*, 1998; Pasqualini & Rouslahti, 1996).

In vivo phage library screening

In vivo phage-display screening of the CX₇C library (C, cysteine; X, any amino acid) (Pasqualini *et al.*, 2000; Arap *et al.*, *Nature Med.* 8:121-127, 2002) for fat-homing peptides was performed (Pasqualini & Rouslahti 1996, Pasqualini *et al.*, 2000). In each biopanning round, an adult ob/ob mouse was injected intravenously (tail vein) with 10¹⁰ transducing units (TU) of the library. Phage (~300 TU/g in round 1 increased to ~10⁴ TU/g in round 3) were recovered after 5 min of circulation by grinding subcutaneous white fat with a glass Dounce homogenizer, suspending the homogenate in 4°C Dulbecco's Modified Eagle's medium (DMEM) containing proteinase inhibitors (DMEM-prn: 1 mM PMSF, 20 µg/ml aprotinin, and 1 µg/ml leupeptin) and washing with DMEM-prn. The lipid phase was discarded during the washes and only the solid-phase cellular material was used. Washed homogenates were incubated with host

bacteria (log phase *E. coli* K91kan; OD₆₀₀ ~ 2). Bacterial cultures were plated onto Luria-Bertani agar plates containing 40 µg/ml tetracycline and 100 µg/ml kanamycin, incubated overnight at 37°C and selected clones were bulk-amplified and used to precipitate phage for a subsequent round of biopanning. The sub-library amplified after the third round of panning was enriched for fat-specific binders using a subtraction step. A lean C57BL/6 female was injected (tail vein) with 10⁹ TU of phage selected in round 3. After 5 min of circulation, the unbound phage were recovered from plasma and amplified for the fourth and final round of biopanning. In this protocol, phage that bound to tissues other than adipose were removed from the sub-library, increasing the selectivity of the recovered phage for binding to adipose tissue.

Peptide localization in tissues

Staining of formalin-fixed, paraffin-embedded mouse tissue sections was performed (Pasqualini & Rouslahti, 1996; Pasqualini *et al.*, 2000). For phage-peptide immunolocalization, 10¹⁰ TU of CKGGRAKDC (SEQ ID NO:22)-phage or a control insertless phage was injected intravenously. Phage immunohistochemistry was performed using a rabbit anti-fd phage antibody (Sigma Chemicals, St. Louis, MO) used at 1:1,000 dilution and a secondary horseradish peroxidase (HRP)-conjugated antibody. Apoptosis was detected using standard TUNEL immunohistochemistry and an HRP-conjugated antibody. For *in vivo* peptide homing validation, stocks of 5-carboxyfluorescein (FITC)-conjugated CKGGRAKDC (SEQ ID NO:22) or CARAC (SEQ ID NO:12) were chemically synthesized, cyclized using the terminal cysteines and HPLC-purified to > 90% purity by Anaspec (San Jose, CA). Lyophilized peptides were dissolved in DMSO to a concentration of 20 mM. Ten µl of 1 mM peptide-FITC solution in PBS was injected 5 min prior to tissue extraction. For blood vessel localization, 10 µl of 2 mg/ml of rhodamine-conjugated lectin-I (RL-1102, Vector Laboratories, Burlingame, CA) was co-injected. All immunohistochemistry and FITC immunofluorescence images were captured using an Olympus IX70 microscope and digital camera setup (Melville, NY).

Anti-obesity therapy

Stocks of CKGGRAKDC (SEQ ID NO:22) fused to (KLAKLAK)₂ (SEQ ID NO:1); (KLAKLAK)₂ (SEQ ID NO:1) alone; CARAC (SEQ ID NO:12) fused to

(KLAKLAK)₂ (SEQ ID NO:1); and CKGGRAKDC (SEQ ID NO:22) peptide were chemically synthesized, cyclized using the terminal cysteines and HPLC-purified to > 90% (Anaspec). Lyophilized peptides were dissolved in DMSO to a concentration of 65 mM to make stock solutions. A total of 150 μ l of 0.65 mM peptide solution in PBS was subcutaneously injected daily in the back of C57BL/6 males, after body mass was measured each day. High-fat cafeteria diet for obesity induction (TD97366: 25.4% fat, 21.79% protein, 38.41% carbohydrate) was purchased from Harlan Teklad. Mice were pre-fed with TD97366 prior to the initiation of treatment with adipose targeting peptides to induce diet-related obesity. The high-fat diet resulted in an average weight of 50 g before treatment.

Results

In vivo phage display (Pasqualini and Ruoslahti., *Nature* 380:364-366, 1996; Kolonin *et al.*, *Curr. Opin. Chem. Biol.* 5:308-313, 2001; Pasqualini *et al.*, *In Vivo Phage Display*, In *Phage Display: A Laboratory Manual*, eds. Barbas *et al.*, pp. 1-24. Cold Spring Harbor Laboratory Press, New York, 2000) was used as described above to obtain a peptide targeting the fat vasculature. A phage-display library was screened for peptide motifs that home to the vasculature of subcutaneous white fat in morbidly obese leptin-deficient (ob/ob) mice (Zhang *et al.*, *Nature* 372:425-432, 1994). This model provides a convenient source of adipose tissue. Four rounds of panning were followed by a fat-specific *in vivo* subtraction to restrict ligands to those binding to adipose-specific endothelial receptors. The DNA encoding the corresponding phage-displayed peptides was then sequenced to obtain the targeting peptide amino acid sequences. Statistical analysis of selected motifs using SAS software (version 8, SAS Institute) revealed that the motif CKGGRAKDC (SEQ ID NO:22) constituted 4.5% of all clones identified in the screen. Intravenous administration of this clone into ob/ob mice showed that CKGGRAKDC (SEQ ID NO:22)-phage accumulated in subcutaneous fat to a higher level than a control insertless phage (data not shown).

The tropism of CKGGRAKDC (SEQ ID NO:22)-phage for adipose tissue was confirmed by immunohistochemistry: CKGGRAKDC (SEQ ID NO:22)-phage showed marked localization to the vasculature of subcutaneous and peritoneal white fat (FIG. 8a, arrows), whereas the control phage was undetectable in fat blood vessels (FIG. 8b). To

test whether targeting of the CKGGRKDC (SEQ ID NO:22) motif to the fat vasculature would also occur when the peptide is outside of the context of the phage, the *in vivo* distribution of intravenously injected CKGGRKDC (SEQ ID NO:22) peptide fused to fluorescent (FITC) was determined. Immunofluorescence in subcutaneous and peritoneal fat from peptide-injected ob/ob mice showed that CKGGRKDC (SEQ ID NO:22)-FITC localized to and was internalized by cells of white adipose vasculature (FIG. 8c, arrows), whereas a control CARAC (SEQ ID NO:12)-FITC conjugate was undetectable in adipose tissue (FIG. 8d).

CKGGRKDC (SEQ ID NO:22) homes to white fat in wild-type mice

The mutation in leptin that leads to the extreme proliferation of white adipose tissue in mice (Zhang *et al.*, 1994) is not frequently encountered in humans (Ozata *et al.*, *J. Clin. Endocrinol. Metab.* 84:3686-3695. 1999). Thus, this animal model may not be representative of the typical pattern of obesity in humans. To exclude the possibility that CKGGRKDC (SEQ ID NO:22) homing to fat is limited to ob/ob mice and to demonstrate the general applicability of adipose-targeting peptides for naturally-occurring obesity, the CKGGRKDC (SEQ ID NO:22) peptide was tested in wild-type mice.

FIG. 9 shows that the CKGGRKDC (SEQ ID NO:22)-FITC fusion peptide intravenously injected into C57BL/6 (leptin +/+) mice specifically localized to blood vessels of subcutaneous and peritoneal white fat (FIG. 9A, FIG. 9B). A lectin-rhodamine peptide was used to visualize blood vessel endothelium (arrows, FIG. 9B, FIG. 9D, FIG. 9F). The CKGGRKDC (SEQ ID NO:22)-FITC fusion peptide co-localized with lectin-rhodamine in adipose tissue (arrows, FIG. 9A and FIG. 9B). No such co-localization was observed in control pancreatic tissue (FIG. 9C and FIG. 9D) or other control organs (data not shown). The control CARAC (SEQ ID NO:12)-FITC peptide was not detectable in white fat vasculature (FIG. 9E and FIG. 9F). These *in vivo* localization data show that the adipose-targeting CKGGRKDC (SEQ ID NO:22) peptide targets the white adipose vasculature in genetically normal obese mice as well as in leptin deficient mice, demonstrating the general applicability of adipose targeting using such peptides. The uptake of CKGGRKDC (SEQ ID NO:22)-FITC by the endothelium of fat tissue suggests that the motif targets a receptor selectively expressed

in the adipose vasculature that could provide a mechanism for directed delivery of therapeutic compounds to fat.

Design and use of fat-targeted pro-apoptotic peptide

It was next determined whether proliferation of adipose tissue could be controlled via targeted destruction of the fat vasculature. The pro-apoptotic peptide KLAKLAKKLAKLAK (SEQ ID NO:1) (Ellerby *et al.*, *Nature Med.* 5:1032-38, 1999) (designated KLAKLAK)₂, which disrupts mitochondrial membranes to induce apoptosis, has been targeted to receptors in tumor vasculature via a conjugated homing peptide (Ellerby *et al.* 1999, Arap, *et al.*, *Proc. Natl. Acad. Sci. U. S. A.* 99:1527-1531, 2002). The (KLAKLAK)₂ (SEQ ID NO:1) peptide was conjugated to the fat targeting CKGGRAKDC (SEQ ID NO:22) peptide for targeted delivery to fat vasculature in adipose tissue. The D enantiomer of (KLAKLAK)₂ (SEQ ID NO:1), which is resistant to proteolysis but still exhibits pro-apoptotic activity, was conjugated to the CKGGRAKDC (SEQ ID NO:22) peptide via a glycylglycine bridge. The conjugated fat-targeting, pro-apoptotic peptide was administered to mice and the effect on adipose tissue was monitored.

A non-genetic mouse obesity model was initially used. A cohort of C57BL/6 (wild-type) mice, in which obesity had been induced by a high-fat cafeteria diet, were subcutaneously injected with CKGGRAKDC (SEQ ID NO:22)-(KLAKLAK)₂ (SEQ ID NO:1) peptide and weighed daily over a period of two weeks. Cafeteria dieting continued throughout the experiment. As shown in FIG. 10A, injections of CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) prevented obesity development and surprisingly caused a rapid decrease in body mass of up to 20%. In contrast, obese mice injected with two negative controls (an equimolar amount of either unconjugated CKGGRAKDC (SEQ ID NO:22) and (KLAKLAK)₂ (SEQ ID NO:1) or a control CARAC (SEQ ID NO:12)-(KLAKLAK)₂ (SEQ ID NO:1) conjugate) did not show a significant body mass decrease and continued to increase in weight (FIG. 10A).

The effectiveness of the CKGGRAKDC (SEQ ID NO:22)-(KLAKLAK)₂ (SEQ ID NO:1) conjugate was also examined in wild-type mice fed on a regular diet (FIG. 10B). C57BL/6 mice that had developed a considerable amount of subcutaneous and

peritoneal fat due to old age were subcutaneously injected with the CKGGRAKDC (SEQ ID NO:22)-(KLAKLAK)₂ (SEQ ID NO:1) conjugate or control peptides over a period of one month. As in the diet-induced obesity model, targeting of (KLAKLAK)₂ (SEQ ID NO:1) to fat by conjugation with CKGGRAKDC (SEQ ID NO:22) resulted in greater than 35% reduction in body mass at a rate of 10% per week (FIG. 10B). No toxicity of the conjugated peptide was detected under these conditions (data not shown). In fact, the CKGGRAKDC (SEQ ID NO:22)-(KLAKLAK)₂ (SEQ ID NO:1) treated mice became more active and agile following body mass reduction and appeared healthier than prior to treatment (data not shown). The control untargeted (KLAKLAK)₂ (SEQ ID NO:1) treatments resulted in only a slight body mass reduction (FIG. 10B), possibly due to low levels of nonspecific toxicity. The control mice did not exhibit the increased activity and/or agility seen in treated mice (data not shown).

Fat resorption with CKGGRAKDC (SEQ ID NO:22)-(KLAKLAK)₂ (SEQ ID NO:1) is mediated by apoptosis

In both diet-induced and age-related obesity, the effect of CKGGRAKDC (SEQ ID NO:22)-(KLAKLAK)₂ (SEQ ID NO:1) treatment on body mass was due to fat resorption, which was visually apparent by the end of treatment (FIG. 11). Wild-type mice were fed on a high fat cafeteria diet (FIG. 11A). Alternatively, wild-type fed on a regular diet became obese as a consequence of old age (FIG. 11B, FIG. 11C, FIG. 11D). Mice were treated with CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) (left side of FIG. 11), with CARAC (SEQ ID NO:12) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) (middle of figure), or with unconjugated CKGGRAKDC (SEQ ID NO:22) and (KLAKLAK)₂ (right side of FIG. 11).

Gross inspection of mouse organs revealed that both subcutaneous (FIG. 11B) and visceral (FIG. 11C) fat exhibited marked resorption upon treatment with CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) (right side of FIG. 11). Quantification of fat resorption after three weeks of treatment by weighing a specific fat depot (epididymal fat, FIG. 11D) showed a greater than 3-fold reduction in fat mass compared with controls (FIG. 11D, left side of figure compared to middle and right side).

Histopathological analysis of tissues from mice treated with CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) showed vascular apoptosis (FIG. 12A, arrows) and resulting fat necrosis with lymphocyte infiltration (FIG. 12C, arrows) in adipose tissue, following treatment. In contrast, mice treated with a control fusion peptide comprising CARAC (SEQ ID NO:12) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) showed no vascular apoptosis or fat necrosis (FIG. 12D). No abnormalities in other organs treated with CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) (data not shown).

Injection of CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1) into genetically obese mice, but not into normal obese mice, was occasionally observed to result in mortality within a few days of injection. It is not clear what the mechanism might be for inducing death in genetically obese mice, although development of pulmonary or cardiac fat embolism or rapid drop of serum calcium due to saponification by released lipids are possibilities. However, these results suggest that treatment of grossly obese subjects might result in sufficient adipose cell death and necrosis to adversely affect the health of the subject, indicating that lower dosages and/or use of a time release formulation of the adipose targeting conjugate may be preferred in cases of excessive obesity.

Adipose receptor protein for CKGGRAKDC (SEQ ID NO:22)

A band of approximately 35,000 Daltons (35 kDa) was isolated from mouse adipose tissue extract that bound to CKGGRAKDC (SEQ ID NO:22) conjugated to (KLAKLAK)₂ (SEQ ID NO:1). There was much less binding of the 35 kDa fraction to the control peptide CARAC (SEQ ID NO:12) conjugated to (KLAKAK)₂ (SEQ ID NO:1) (data not shown). The 35 kDa band was analyzed by mass spectrometry, which identified three proteins present in the sample.

The three proteins included predominately a B cell receptor associated protein (prohibitin), apolipoprotein E, and the voltage dependent anion channel (VDAC). Further studies were performed by immunoprecipitation, using either CKGGRAKDC (SEQ ID NO:22) or CARAC (SEQ ID NO:12) conjugated to (KLAKAK)₂ (SEQ ID NO:1) and precipitating with commercially available antibodies.

SDS-polyacrylamide gel electrophoresis of the immunoprecipitated protein showed that only the prohibitin receptor protein complex was substantially enriched by binding to CKGGRAKDC (SEQ ID NO:22) (data not shown), with over a ten-fold enrichment in the CKGGRAKDC (SEQ ID NO:22) precipitated fraction compared to the CARAC (SEQ ID NO:12) precipitated fraction (data not shown). The CARAC (SEQ ID NO:12)-(KLAKAK)₂ (SEQ ID NO:1) fusion peptide exhibited low levels of non-specific binding to all three proteins (VDAC, prohibitin and apolipoprotein E). It is unknown whether those proteins bound to the CARAC (SEQ ID NO:12) moiety or to (KLAKAK)₂ (SEQ ID NO:1).

It is concluded that the adipose tissue endothelial receptor for CKGGRAKDC (SEQ ID NO:22) is prohibitin (Genbank Accession No. NM_008831). Prohibitin is expressed in mitochondria of various cell types and in the cell membrane of B lymphocytes. Immunohistochemical analysis shows that prohibitin is expressed in blood vessels of adipose tissues but not of other organs (data not shown). Based on these results, it is concluded that pro-apoptosis agents conjugated to targeting peptides that bind to a prohibitin receptor protein complex are effective to induce adipose cell death and weight loss in obese subjects. The skilled artisan will realize that other prohibitin-binding targeting peptides, antibodies, *etc.* may be used within the scope of the claimed methods and compositions to control weight and/or to induce weight loss. Further, other known cytotoxic, cytotoxic and/or cytostatic agents may be used in place of (KLAKAK)₂ (SEQ ID NO:1) to control weight or induce weight loss within the scope of the claimed subject matter.

Example 5: Screening an alpha-spleen antibody library *in vivo* by BRASIL

[0192] The following Examples are illustrative of general techniques that may be of use in various embodiments of the claimed invention. As part of the reticulo-endothelial system, biopanning against spleen tissue is complicated by the high background of non-specific phage localization to spleen. The decreased background observed in biopanning with the BRASIL method is advantageous for identifying targeting peptides against tissues such as spleen.

[0193] This example demonstrates an illustrative embodiment of the BRASIL method. A phage library based on immunoglobulins derived against the target organ

(mouse spleen) was developed and then subjected to *in vivo* biopanning. To construct the immunoglobulin library, mouse spleen was injected into a chicken. After boosting, the chicken spleen was collected and immunoglobulin variable domain sequences were obtained by PCRTM amplification of chicken spleen mRNA. The amplified immunoglobulin variable sequences were inserted into a phage display library (α -library) that was then used for *in vivo* biopanning against mouse spleen. Thus, the spleen targeting peptide sequences obtained from phage localized to mouse spleen *in vivo* were derived from antibody fragments produced in the chicken in response to mouse spleen antigens. The success of this example further shows the broad utility of the BRASIL method. The skilled artisan will realize that the present invention is not limited to the embodiments disclosed herein and that many further developments of the BRASIL methodology are included in the scope of the present invention.

Materials and Methods

Library construction

[0194] A white leghorn chicken was immunized with spleen homogenate (about 150 mg per injection) from a perfused (10 ml MEM) Balb/c mouse. The chicken received spleen homogenate boosters at 4 weeks and 8 weeks after the initial immunization. Immune response to mouse spleen by FACS analysis showed that the chicken immune serum contained antibodies against a mouse cell-line (TRAMP-C1). The chicken was sacrificed and its spleen was removed to TRI Reagent (Molecular Research Center, Inc., Cincinnati, OH) 12 weeks after the first immunization.

[0195] Total RNA was prepared from the chicken spleen using the manufacturer's protocol for the TRI reagent. cDNA was prepared from the total RNA using oligo (dT)-primers and Superscript enzyme (Life Technologies, Gaithersburg, MD). cDNAs encoding chicken spleen immunoglobulin variable regions were amplified by CHyBVH and ChyBIgB (V_{heavy}) or by CSCVK and CHHybL-B (V_{kappa}) primers according to standard techniques. Light chain variable regions and constant regions were PCRTM amplified together using CSC-F and lead-B primers and V_{kappa} and C_{kappa} templates. Heavy chain variable regions and constant regions were PCRTM amplified together using dp-seq and lead-F primers and V_{heavy} and C_{heavy} templates. Heavy- and light-chain fragments were PCRTM amplified together with CSC-F and dp-Ex primers. PCR primers

were purchased from Genosys (The Woodlands, TX) or GenBase (St. Lucia, Queensland, Australia), using primer sequences listed in the Cold Spring Harbor laboratory course manual, "Phage Display of Combinatorial Antibody Libraries" (Barbas *et al.*, 2000), the relevant text of which is incorporated herein by reference.

[0196] After digestion with Sfi I, the amplification products were ligated to SfiI - digested pComb3x for insertion into the phage library. Ligated pComb3-123 plasmid was electroporated into ER2537 *-E.coli* and phage production was started with subsequent VCM13 (helper phage) infection. The resulting library size was about 5×10^6 cfu.

In vivo screening of α -spleen library using BRASIL

[0197] Four rounds of *in vivo* screening in mice were performed using the chicken α -spleen library. About 0.8 to 2.0×10^{10} TU were injected into a Balb/c mouse. The library was allowed to circulate for 5 minutes. After sacrifice, the mouse spleen was recovered and a single cell suspension was prepared by pressing the spleen through a $70 \mu\text{m}$ cell strainer nylon mesh. The single cell suspension was centrifuged over oil (9:1 dibutyl phthalate: cyclohexane) using the BRASIL technique and $200 \mu\text{l}$ of log phase ER2537 *E. coli* were infected with the pellet. Amplified phage recovered from the mouse spleen was used for the subsequent round of screening. No obvious enrichment in the screening rounds was seen in the number of phage homing to spleen and brain compared with the conventional biopanning method, using a piece of spleen obtained prior to BRASIL.

[0198] Phage localized in mouse spleen from the fourth round of screening of the chicken Fab inserts were PCRTM amplified and the PCR product was digested with *Bst* I. Half of the clones out of 90 analyzed produced a similar restriction pattern. Of those, 20 clones were sequenced from which only two had an identical restriction pattern. Four of the antibody based phage clones (numbers 2, 6, 10 and 12) were subjected to further analysis using binding and localization assays.

Testing the clones in vitro using BRASIL

[0199] A single cell suspension was prepared from two mouse spleens. The suspension was divided into five tubes and incubated on ice with 3×10^9 TU of Fab clones #2, #6, #10, #12 and 2×10^9 TU tet-phage. Phage bound to mouse spleen cells were

recovered by BRASIL. 200 μ l of log phase ER2537 *E.coli* was infected with the pellet and serial dilutions were plated on LB/carbenicillin and LB/tetracycline plates for assessment of phage binding. Fd-tet was used as an internal control to normalize all the phage homing experiments.

Testing clones in vivo with BRASIL

Phage (3×10^9) of Fab clones #2, #6, #10, #12 and 2×10^9 TU tet-phage were injected into the tail veins of Balb/c mice and allowed to circulate for 5 minutes. The spleens were recovered and single cell suspensions were prepared on ice from whole spleens. Cell bound phage were recovered by BRASIL. 200 μ l of log phase ER2537 *E.coli* was infected with the pellet and serial dilutions were plated on LB/carbenicillin and LB/tetracycline plates for assessment of the phage recovery.

Testing clone #10 versus, control phage NPC-3TT in vivo with BRASIL

Phage (3×10^9 TU) of Fab clone #10 and NPC-3TT (control Fab phage) and 1×10^9 TU of control Fd-tet -phage were injected to mice (2 mice for NPC-3TT, 2 mice for clone #10) and allowed to circulate for 5 minutes. Spleens were recovered and single cell suspensions were prepared on ice. Cell-bound phage were recovered by BRASIL. 200 μ l of log phase ER2537 *E.coli* was infected with the pellet and serial dilutions were plated on LB/carbenicillin and LB/tetracycline plates. The NPC-3TT phage is a human anti-tetanus toxin Fab fragment displaying phage.

Homing of Fab clone #10 to spleen versus bone marrow

Phage (3×10^9 TU) of Fab clone #10 and NPC-3tt control and 1×10^9 TU of Fd-tet control phage were injected into mice (2 mice for NPC-3TT, 2 mice for clone #10) and allowed to circulate for 5 minutes. The spleens were recovered and single cell suspensions were prepared. Bone marrow was recovered from the same mice (both femurs) as a control for organ specific homing. Cell-bound phage were recovered by BRASIL.

Fab -fragment production

[0200] The plasmid pComb3 containing the chicken Fab inserts was electroporated into ER2537 bacteria. Serial dilutions were plated onto LB/carbenicillin plates and incubated overnight at 37°C. Fab production culture (in super broth with 100 μ g/ml

carbenicillin) was started from a single plated colony. Fab production was induced with 1 mM IPTG for 7 hours at 30°C. The Fab fragment was purified from the periplasmic fraction SN2 by affinity purification after determination of the Fab concentration in bacteria supernatant, periplasmic fractions SN1 and SN2 and in the bacteria lysate by ELISA. An α -Fab-Protein G -column was coupled (2 mg/ml) with dimethylpimelimidate (DMP) using standard protocols (Harlow and Lane, Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory Press, New York, NY, 1988).

[0201] For purifying Fab fragments the following method was used. The SN2 fraction was loaded into a 1 ml HiTrap-protein G- α -Fab-column (Amersham Pharmacia Biotech, Piscataway, NJ) either over 2 hours (if using lower than 50 ml volume with superloop) or overnight (with more than 50 ml volume using a peristaltic pump). The column was washed with 10-20 ml of PBS (phosphate buffered saline). The Fab fragments were eluted with 10 ml of 20 mM glycine buffer, pH 2.2, 150 mM NaCl and 1 ml fractions were collected. Fractions are neutralized with 1 M Tris immediately after elution. Protein concentrations were quantified by A₂₈₀.

Intravascular staining

[0202] To determine *in vivo* distribution of the recovered Fab fragments, 50 to 60 μ g of Fab fragment (Fab#10, NPC3-tt or R#16) was injected into the tail vein of a Balb/c mouse and allowed to circulate for 8 minutes. 50 μ g of *L. esculentum* lectin-FTTC was injected into the mouse and the mouse tissues were fixed by perfusion with 25 to 30 ml of 4% paraformaldehyde/PBS after 2 minutes of lectin circulation. Tissues were removed and post-fixed in 4% paraformaldehyde for 1 hour. Fixed tissues were incubated in 30% sucrose/PBS overnight at 4°C, changing the solution at least twice. The tissues were embedded in the freezing media and frozen on dry ice.

[0203] Fixed tissue sections were stained for Fab as follows. Frozen tissue sections (55 μ m) were cut on a microtome and washed 3x with PBS. The thin sections were blocked with PBS/0.3%TritonX-100/5% goat serum for 1 hr at room temperature. Sections were incubated overnight at room temperature with 1:400 Cy3 conjugated α -human anti-Fab antibody. The conjugated sections were washed 6x with PBS/0.3% Triton X-100, 3x with PBS, and fixed with 4% paraformaldehyde for 15 minutes. After

fixation the sections were washed again 2x with PBS and 2x with distilled water, then mounted on slides using VectorShield.

Results

[0204] The *in vitro* localization to mouse spleen cells of phage clones expressing chicken Fab fragments was examined by BRASIL. As shown in FIG. 13, the Fab phage clones isolated by BRASIL showed differential binding to mouse spleen cells compared to Fd-tet insertless control phage. Clone #6 showed the lowest degree of binding, similar to the control phage NPC-31T, which contained a Fab fragment but was not isolated from mouse spleen. Clones #2, #10 and #12 all showed selective binding to mouse spleen cells compared to the Fd-tet control, with at least a two-fold increased binding observed for clones #2 and #10 (FIG. 13). The amino acid sequences determined for the clone inserts were:

Clone #2:

CQPAMAAVILDESGGGLQTPGGALSLVCKASGFTFNSYPMGWVRQAPG
KGLEWVA VISSSGTTWYAPAVKGRATISRDNQSTVRLQLSNLRAED
(SEQ ID NO:23)

Clone #6:

CQPAMAAVILDESGGGLQTPGGTILSLVCKASGISIGYGMNWWVRQAPGK
GLEWVASISGDGNFAHYGAPVKGRATISRDDGQNTVTLQLNNLR (SEQ
ID NO:24)

Clone #10:

CQPAMAAVILDESGGGLQTPGGTILSLVCKGSGFTFSRYDMAWVRQAPG
KGLEWVAGIDGGGYTTLYAPAVKGRATITSRDNQSTVRLQLNNLR
(SEQ ID NO:25)

Clone #12:

ANQPWPPLTLDESGGGLQTPGGALSLVCKASGFTMSSYDMFWVRQAPG
KGLEFVAGISSGSSTEYGA AVKGRATISRDNQSTVRLQLNNLRAED
(SEQ ID NO:26)

[0205] A direct comparison was made of *in vitro* phage binding for the Fab clones compared to NPC-3TT. As shown in FIG. 14, clones #2 and #10 exhibited the highest levels of binding to mouse spleen cells *in vitro*. Clones #6 and #12 showed levels of binding to mouse spleen that were only slightly higher than the binding of phage NPC-3TT.

[0206] The preferential binding of the chicken Fab phage clones was confirmed by *in vivo* studies using BRASIL. As shown in FIG. 15, selective localization to mouse spleen was even more dramatic *in vivo*, with Fab clones #2, #6 and #10 showing many-fold increased binding to spleen compared to Fd-tet phage. In contrast, Fab clone #12 did not exhibit significantly elevated binding to mouse spleen compared to Fd-tet phage. These results show that *in vitro* results obtained with spleen targeting phage are confirmed *in vivo*.

[0207] Fab clone #10 was selected for additional characterization by *in vivo* localization to mouse spleen. The results, shown in FIG. 16, confirm that Fab clone #10 exhibited 3 to 10 fold enrichment in spleen compared to Fd-tet. This effect was not due to general Fab binding, since the Fab control phage NPC-3TT did not exhibit selective localization in spleen compared to Fd-tet insertless phage.

[0208] Binding of Fab clone #10 was organ specific, as demonstrated in FIG. 17. Phage from Fab clone #10 and NPC-3TT control were recovered from spleen and bone marrow tissue from the same injected mice. It can be seen in FIG. 17 that Fab clone #10 exhibited selective localization to spleen but not to bone marrow tissue. The control phage did not exhibit selective localization to bone marrow (FIG. 17) or spleen (not shown).

[0209] These results show that Fab phage clone #10 selectively targets mouse spleen tissue for binding both *in vitro* and *in vivo*. These results were further validated by vascular staining for *in vivo* phage distribution. Control phage used for this study were clones NPC-3TT (Fab fragment) and clone R#16 (isolated from angiogenic retina screening).

[0210] Fab clone #10 was observed to bind to mouse spleen tissue *in vivo* by fluorescent staining (not shown). The control phage NPC-3TT and R#16 did not stain spleen tissue under identical conditions (not shown). The clone #10 and NPC-3TT

phage were observed to intensively stain kidneys of injected animals, perhaps due to glomerular filtration (not shown). Other control organs (lung, brain, liver, heart and skeletal muscle) did not show staining with clone #10 (not shown).

[0211] These results demonstrate that spleen targeting phage peptides can be identified by the BRASIL method. They further show the feasibility of the phage display technique using antibody fragments against a target organ, tissue or cell type to obtain a starting phage library. The ability to obtain targeting peptides against spleen, a tissue that has proven refractory to biopanning using standard phage display protocols because of the high non-specific background, shows the advantages of the BRASIL method.

Example 6. Identification of Receptor/Ligand Pairs: Targeting Peptides against Integrin Receptors

[0212] Certain embodiments of the present invention concern the identification of receptor/ligand pairs for various applications. Targeting peptides selective for organs, tissues or cell types bind to receptors (as defined above), normally located on the luminal surface of blood vessels within the target. In certain embodiments, targeting peptides may be used to identify or characterize such receptors, either directly or indirectly. In addition to their use as targets for delivery of gene therapy vectors, other therapeutic agents or imaging agents for *in vivo* imaging, such naturally occurring receptors are of use as potential targets for development of new therapeutic agents directed against the receptor itself, for development of vaccines directed against the receptor, and for understanding the molecular mechanisms underlying various disease states. Naturally, the targeting peptides themselves may serve as the basis for new therapeutic agents directed against the receptors.

[0213] Targeting peptides may frequently act as mimetopes of endogenous ligands that bind to the targeted receptor. In other embodiments, the endogenous ligands may be identified and characterized using the disclosed methods. Such ligands are also of potential use as targets for development of new therapeutic agents, *etc.*

[0214] The present example illustrates one embodiment related to identification of receptor/ligand pairs, in this case, integrin receptors. Non-limiting examples of applications of targeting peptides directed against integrins include regulation of cell proliferation and chemotaxis, pro-apoptosis and anti-angiogenesis. In this embodiment,

purified integrins attached to a solid substrate were used to screen phage display libraries to identify targeting peptides directed against integrins.

Background

[0215] Integrin function is regulated by cytokines and other soluble factors in a variety of biological systems. Most commonly, exposure to such factors leads to conformational alterations that result in changes in the activation state of the receptors (i.e., increased or decreased affinity for a given ligand and/or receptor clustering in the plasma membrane). Changes in integrin-dependent adhesion ultimately activate various complex signal transduction pathways. At the molecular level, the induced co-localization of cytoskeleton proteins with integrin cytoplasmic domains controls signal transduction.

[0216] Cytoplasmic domains are key regulators of integrin function (reviewed in Hynes, *Cell* 69:11-25, 1992; Ruoslahti, *Ann. Rev. Cell Dev. Biol.* 12:697-715, 1996). Individual α and β subunit cytoplasmic domains are highly conserved among different species (Hemler *et al.*, *In: Integrins: The Biological Problems*, ed. Takada, CRC Press, Inc. Boca Raton, FL, pp. 1-35, 1994). Although the cytoplasmic domains of various β subunits share similar primary structures, they differ in certain functional characteristics. Experiments with chimeric integrins have shown that the cytoplasmic domains of β chains are responsible for regulating receptor distribution and recruitment to focal adhesion sites (Pasqualini and Hemler, *J. Cell. Biol.* 125:447-460, 1994). Thus, certain cytoplasmic domains are critical for integrin-mediated signaling into the cell (outside-in signaling) and activation of integrin-ligand binding activity (inside-out signaling) (Hemler *et al.*, 1994).

[0217] The integrins $\alpha v\beta 3$ and $\alpha v\beta 5$ are selectively expressed in angiogenic vasculature but not in normal vasculature (Brooks *et al.*, 1994a, 1994b; Pasqualini *et al.*, 1997; Arap *et al.*, 1998). Moreover, αv integrin antagonists have been shown to block the growth of neovessels (Brooks *et al.*, 1994a, 1994b, 1995; Hammes *et al.*, 1996). In these experiments, endothelial cell apoptosis was identified as the mechanism for the inhibition of angiogenesis (Brooks *et al.*, 1994a, 1994b, 1995). Angiogenesis initiated by bFGF can be inhibited by an anti- $\alpha v\beta 3$ blocking antibody, whereas VEGF-mediated angiogenesis can be prevented by a blocking antibody against $\alpha v\beta 5$. The integrins $\alpha v\beta 3$

and $\alpha v\beta 5$ have been reported to be preferentially displayed in different types of ocular neovascular disease (Friedlander *et al.*, 1995, 1996). Thus, distinct cytokine-induced pathways that lead to angiogenesis seem to depend on specific αv integrins.

[0218] The search for αv integrin-associated molecules has been hampered by technical difficulties. First, the physical associations involved are likely to rely on an assembly of multimeric ligands that no longer occurs when cells are not intact. Second, their association to integrins is usually of low affinity. Finally, changes in the conformation and phosphorylation states of the associating proteins may add a further level of complexity in these transiently modulated interactions. Because of these problems, only a limited number of proteins that bind to integrin cytoplasmic domains have been identified. These proteins, such as paxillin and ICAP-1, mainly associate with the $\beta 1$ chain (Shattil and Ginsberg, 1997). Cytohesin-1 and filamin associate with the cytoplasmic domain of $\beta 2$.

[0219] The disclosed methods have several advantages over previous approaches: (i) the ability to characterize the intracellular molecules that directly or indirectly interact with integrin cytoplasmic domains; (ii) the development of antibodies against molecules that bind to integrin cytoplasmic domains in very low amounts; and (iii) the phage display library screenings will lead to the identification of peptides that mimic cytoplasmic-domain binding proteins.

Methods

Two dimensional cell culture

[0220] Three human endothelial cell lines that express $\beta 3$ and $\beta 5$ integrins were used: KS1767 cells (Herndier *et al.*, 1996), HUVECs (ATCC), and BCE cells (Solowska *et al.*, 1991). Sterile glass coverslips covered with different proteins (i.e. vitronectin, fibronectin, collagen, or laminin) were used as substrates. After cells attached and spread, the monolayers were rendered quiescent by a 12-hour incubation in medium containing 0.05% fetal calf serum. Peptides were introduced into the cells using the penetratin membrane-permeable tag (see below). The cells were plated onto ECM proteins for adhesion and spreading. The monolayer was stimulated for 6 hours with

each of the growth factors involved in αv -mediated angiogenesis, including bFGF, TNF α , VEGF, and TGF β . Untreated cells were the negative controls.

Three-Dimensional Cell Culture:

[0221] 150 μ l of Matrigel were added per well of 24-well tissue culture plates and allowed to gel at 37°C for 10 min. HUVECs starved for 24 h in M199 medium supplemented with 2% FCS before being trypsinized were used. 10^4 cells were gently added to each of the triplicate wells and allowed to adhere to the gel coating for 30 min at 37°C. Then, medium was replaced with peptides in complete medium. The plates were monitored and photographed after 24 h with an inverted microscope (Canon).

Chemotaxis Assay:

[0222] Cell migration assays were performed as follows: 48-well microchemotaxis chambers were used. Polyvinylpyrrolidone-free polycarbonate filters (Nucleopore, Cambridge, MA) with 8- μ m pores were coated with 1% gelatin for 10 min at room temperature and equilibrated in M199 medium supplemented with 2% FCS. Peptides were placed in the lower compartment of a Boyden chamber in M199 supplemented with 2% FCS, 20 ng/ml VEGF-A (R&D System), and 1 U/ml heparin. Overnight-starved subconfluent cultures were quickly trypsinized, and resuspended in M199 containing 2% FCS at a final concentration of 2×10^6 cells/ml. After the filter was placed between lower and upper chambers, 50 μ l of the cell suspension was seeded in the upper compartment. Cells were allowed to migrate for 5 h at 37°C in a humidified atmosphere with 5% CO₂. The filter was then removed, and cells on the upper side were scraped with a rubber policeman. Migrated cells were fixed in methanol and stained with Giemsa solution (Diff-Quick, Baxter Diagnostics, Rome, Italy). Five random high-power fields (magnitude 40 \times) were counted in each well.

Proliferation Assay:

[0223] Cell proliferation was measured as described (Pasqualini and Hemler, 1994). Briefly, 4×10^4 HUVECs were incubated in 24-wells plates. The cells were starved for 24 h, and then the medium was removed and replaced in the presence of VEGF and 15 μ M of each peptide and incubated for 18 h. Then, 50 μ l of media containing [³H]thymidine (1 μ Ci/ml) was added to the wells, and after 6 additional hours of incubation at 37°C, the

medium was removed and the cells were fixed in 10% TCA for 30 min at 4°C, washed with ethanol, and solubilized in 0.5 N NaOH. Radioactivity was counted by liquid scintillation with an LS 6000SC Beckman scintillation counter. Each experiment was performed three times with triplicates, and the results are expressed as the mean \pm SD.

Apoptosis Assay (propidium iodide staining subdiploid population)

[0224] Approximately 1×10^6 cells were harvested in complete media and 15 μ M of peptide added for 4, 8, or 12 h. The cells were then washed in PBS and resuspended in 0.5 ml propidium iodide solution (50 μ g/ml PI, 0.1% Triton X-100, 0.1% sodium citrate). After a 24-h incubation at 4°C, cells were counted with a XL Coulter (Coulter Corporation) with a 488-nm laser; 12,000 cells were counted for each histogram, and cell cycle distributions were analyzed with Multicycle program.

[0225] After microinjection or penetratin-mediated internalization of the peptides and appropriate controls, cell apoptosis was monitored using the ApopTag kit. Experiments were performed in the presence of caspase inhibitors and antibodies against specific caspases.

Cytokine- and Tumor-Induced Angiogenesis Assays

[0226] Angiogenic factors and tumor cells implanted into CAM stimulate growth of new capillaries. Angiogenesis was induced in CAMs from 10-day chicken embryos by VEGF or bFGF filters implanted in regions that were previously avascular. Different treatments (penetratin peptides and controls) were applied topically, and after 3 days, the filters and surrounding CAMs were resected and fixed in formalin. The number of blood vessels entering the disk was quantified within the focal plane of the CAM with a stereomicroscope. The mean number of vessels and standard errors from 8 CAMs in each group were compared.

Phosphorylation and panning of phosphorylated phage libraries

[0227] Phosphorylation of peptide libraries with src family protein kinases (Fyn, c-Src, Lyn, and Src) and serine/threonine kinases such as a MAP kinase were performed as described previously (Schmitz *et al.*, 1996; Dente *et al.*, 1997; Gram *et al.*, 1997). Briefly, phage particles were collected from culture supernatants by double precipitation with 20% polyethylene glycol 8000 in 2.5 M NaCl. Particles were dissolved at 10^{12}

particles/ml. Purified phage (10 μ l) were incubated for 3 hours at room temperature with different concentrations (35 to 3,500 units) of protein kinases in a reaction buffer volume of 50 μ l. The reaction mixtures were transferred to tubes containing 10 μ g of agarose-conjugated anti-P-Tyr, anti-P-Ser, or anti-P-Thr monoclonal antibodies to select phage displaying phosphorylated peptides. Bound phage were eluted by washing the column with 0.3 ml of elution buffer (0.1 M NaCl/glycine/1 mg/ml BSA, pH 2.35). The eluates were neutralized with 2 M Tris-base and incubated with 2 ml of a mid-log bacteria culture. Aliquots of 20 μ l were removed for plating, and phage were harvested as described. The phosphorylation-selection step was repeated. Phosphorylated peptides binding to β 3 and β 5 cytoplasmic domains were analyzed as described in the previous section.

[0228] Matrix-assisted laser desorption time-of-flight (MALDI-TOF) mass spectrometry was used to map *in vitro* phosphorylation sites on the β 3 and β 5 cytoplasmic domains and cytoplasmic domain-binding peptides. The fusion proteins or peptides were phosphorylated *in vitro* as described and purified by RP-HPLC or RP microtip columns. Phosphorylated peptides were identified by three methods: (1) 80-Da mass shifts after kinase reactions; (2) loss of 80 Da after phosphatase treatment; or (3) loss of 80 Da or 98 Da in reflector vs. linear mode for tyrosine phosphorylated or serine, threonine phosphorylated peptides, respectively. Where needed, peptides were purified by RP-HPLC and subjected to carboxypeptidase and aminopeptidase digestions to produce sequence ladders. This was particularly useful where one peptide may harbor two or more phosphorylation sites.

Panning on phosphorylated GST-fusion proteins.

[0229] GST fusion proteins were phosphorylated *in vitro* as described (Schmitz *et al.*, 1996; Dente *et al.*, 1997; Gram *et al.*, 1997). Briefly, 10 $\mu\text{g/ml}$ was incubated for 3 h at room temperature with 5.5 units of Fyn protein kinase in reaction buffer (50 mM Tris, 5mM MgCl_2 , 500 μM Na_3VO_4 , 500 μM ATP in a total volume of 50 μl). The reaction was stopped by adding 40% of TCA. After the kinase substrate protein was precipitated, it was resuspended in PBS and coated on microtiter wells at 10 $\mu\text{g/well}$. An aliquot of CX₇C library (2.5×10^{11} transducing units) was incubated on the GST fusion proteins. Phage were sequenced from randomly selected clones.

Mass Spectrometry Studies

[0230] Mass spectrometric peptide mass mapping was used to identify novel ligands for $\beta 3$ and/or $\beta 5$ cytoplasmic domains. Polyclonal and monoclonal antibodies raised against the cytoplasmic domain-binding peptides were used to purify target proteins (cytoskeletal or signaling molecules). These proteins were resolved by SDS-PAGE, cut out from the SDS gels, and digested in-gel with trypsin. After extraction of the peptides, MALDI-TOF mass spectrometry analysis was performed to produce a list of peptide masses. This list of peptide masses, in combination with protease specificity, produces a relatively specific "signature" that can be used to search sequence databases. If the protein sequence is present in a database, the protein can be identified with high confidence by this method. The lower detection limit for this approach is currently 1 pmol, at least 10–20-fold better than N-terminal Edman sequencing methods.

Results

Panning of phage peptide libraries on $\beta 3$ or $\beta 5$ cytoplasmic domains.

[0231] $\beta 3$ and $\beta 5$ cytoplasmic domain-binding peptides were isolated by screening multiple phage libraries with recombinant GST fusion proteins that contained either GST- $\beta 3\text{cyto}$ or GST- $\beta 5\text{cyto}$ coated onto microtiter wells. Immobilized GST was used as a negative control for enrichment during the panning of each cytoplasmic domain. Phage were sequenced from randomly selected clones after three rounds of panning as disclosed elsewhere (Koivunen *et al.*, Biotechnology 13:265-270, 1995; Pasqualini *et al.*, 1995). Distinct sequences were isolated that interacted specifically with the $\beta 3$ or with

the $\beta 5$ cytoplasmic domains (Table 4). Randomly selected clones from panning rounds II and III were sequenced. Amino acid sequences of the phagemid encoded peptides were deduced from nucleotide sequences. The most frequent motifs found after panning with the indicated libraries are shown in Table 4. The ratios were calculated by dividing the number of colonies recovered from $\beta 3$ -GST-coated wells and those recovered from GST or BSA.

[0232] The specificity of the interaction with $\beta 3$ or $\beta 5$ cytoplasmic domains was determined by calculating the ratios of phage bound to the cytoplasmic domain containing-fusion proteins ($\beta 3$ or $\beta 5$) versus GST alone (negative control). FIG. 18 shows the results from binding assays performed with the GST- $\beta 3$ cyto binding phage. Six phage were tested that displayed the motifs most frequently found during the second and third rounds of panning. Each panel shows the results from binding assays for the phage displaying different peptides that bind to the $\beta 3$ cytoplasmic domain, as indicated. Insertless phage or unselected libraries were used as negative controls and did not show binding above background. Two plating dilutions were shown for each assay.

[0233] A similar strategy was used to determine the specificity of the phage isolated in the screenings involving the $\beta 5$ cytoplasmic domain fusion protein. The binding assays were performed with individually amplified phage, shown in FIG. 19. Five phage were tested that displayed the motifs found most frequently during the second and third rounds of panning. Each panel shows the binding assays for the phage displaying peptides that bind to the $\beta 5$ cytoplasmic domain. Insertless phage or unselected libraries were used as negative controls and did not show binding above background in these assays.

[0234] To determine whether the binding of the selected motifs was specific for each cytoplasmic domain, binding assays were performed comparing the interaction of individual phage motifs with $\beta 1$, $\beta 3$, or $\beta 5$ cytoplasmic domain fusion proteins. ELISA with anti-GST antibodies showed that the three proteins can be coated onto plastic at equivalent efficiency, and thus the differences in binding do not reflect differences in coating concentrations (not shown). Both the $\beta 3$ - and $\beta 5$ -selected phage selectively

interacted with the proteins on which they were originally selected, with average binding selectivities observed of $\beta 3/\beta 1 = 3.9$, $\beta 3/\beta 5 = 3.7$, $\beta 5/\beta 1 = 4.8$, and $\beta 5/\beta 3 = 6.9$ (not shown). The average selectivity for integrin cytoplasmic domains versus BSA was about one to two orders of magnitude (not shown). None of the phage tested seemed to bind strongly to the $\beta 1$ cytoplasmic domain (not shown).

Characterization of synthetic peptides corresponding to the sequences displayed by the integrin-cytoplasmic domain-binding phage.

[0235] Specific phage were selected for further studies on the basis of their binding properties. Synthetic peptides corresponding to the sequence displayed by each phage were used to perform binding inhibition studies. This assay determined whether phage binding was entirely mediated by the targeting peptide displayed by the phage or whether it also included a non-specific component. As expected, the synthetic peptides inhibited the binding of the corresponding phage in a dose-dependent manner (FIG. 20 and FIG. 21). A control peptide containing unrelated amino acids had no effect on phage binding when tested at identical concentrations.

Phosphorylation events modulate the interaction of the selected peptides with cytoplasmic domains

[0236] Events involving phosphorylation are important in regulating signal transduction. The phage display system was used to evaluate the effect of tyrosine phosphorylation at two levels. First, recombinant fusion proteins containing $\beta 3$ or $\beta 5$ cytoplasmic domains were used for panning of phage libraries displaying tyrosine-containing peptides. Second, the cytoplasmic domains themselves were phosphorylated before phage selection was performed. Experiments were performed to investigate the capacity of specific tyrosine kinases to modulate the interaction of the selected peptides with the cytoplasmic domains. The results obtained in the panning of phage libraries displaying tyrosine-containing peptides are shown in Table 5.

[0237] Randomly selected clones from rounds III and IV were sequenced from a X_4YX_4 phosphorylated library with Fyn. Amino acid sequences of the phagemid encoded peptides were deduced from nucleotide sequences. Table 5 shows the motifs found most frequently after the indicated libraries were panned with $\beta 3$ or $\beta 5$. The ratio

of binding to $\beta 3$ or $\beta 5$ was calculated by dividing the number of $\beta 3$ or $\beta 5$ colonies by GST or BSA colonies found after panning. The ratio of binding to $\beta 3$ or $\beta 5$ with phosphorylated phage by Fyn versus unphosphorylated phage was calculated by dividing the number of colonies found after the panning.

Table 5. Sequences displayed by phosphorylated phage binding to integrin cytoplasmic domains.

Peptide Motif		Phos/Unphos	$\beta 3$ or $\beta 5$ /GST	$\beta 3$ or $\beta 5$ /BSA
<u>$\beta 3$ cytoplasmic</u>				
GGGSYRHVE	SEQ ID NO:49	13.2	1.5	5.3
RAILYRLAN	SEQ ID NO:50	2.8	1.3	20
MLLGYRFEK	SEQ ID NO:51	2.5	3.5	2.7
<u>$\beta 5$ cytoplasmic</u>

TMLRYFMFP	SEQ ID NO:53	4.2	2.3	3.8
TLRKYFHSS	SEQ ID NO:54	3.8	3.8	15.2

[0238] The effect of phosphorylation on the affinity and specificity of the cytoplasmic domain-binding was examined. Phage displaying the $\beta 3$ and $\beta 5$ cytoplasmic domain-binding peptides were phosphorylated *in vitro* as previously described (Schmitz *et al.*, 1996; Dente *et al.*, 1997; Gram *et al.*, 1997), using Fyn kinase. Specific phosphorylation of the tyrosine-containing peptide on the surface of the phage was confirmed by using ^{32}P -gamma dATP in the kinase reaction and by separating the phage pIII protein by SDS-PAGE.

[0239] Phage phosphorylated *in vitro* showed increased binding affinity and specificity to the $\beta 3$ integrin cytoplasmic domain (FIG. 22). The TLRKYFHSS (SEQ ID NO:54) phage was also tested in assays that included other GST-cytoplasmic domain fusion proteins to determine specificity (FIG. 23).

Sequence similarity of integrin binding peptides with known cytoskeletal and signaling proteins.

[0240] The peptides displayed by integrin cytoplasmic domain-binding phage were similar to certain regions found within cytoskeletal proteins and proteins involved in

signal transduction (Table 6). The similarity of some of the isolated peptides to a region of mitogen-activated protein kinase 5 (MAPK5, amino acids 227-234) was particularly interesting. A connection involving the MAPK cascade, cell adhesion, migration and proliferation has been proposed (Lin *et al.*, 1997)

Table 6. Sequence similarity of integrin binding peptides with known cytoskeletal and signaling proteins.

Membrane-permeable peptides

[0241] Penetratin is a peptide that can translocate hydrophilic compounds across the plasma membrane. Fusion to the penetrating moiety allows oligopeptides to be targeted directly to the cytoplasm, nucleus, or both without apparent degradation (Derossi *et al.*,

1994). This membrane-permeable peptide consists of 16 residues (RQIKIWFQNRRMKWKK, SEQ ID NO:55) corresponding to amino acids 43–58 of the homeodomain of Antennapedia, a *Drosophila* transcription factor (Joliet *et al.*, 1991a, 1991b; Le Roux *et al.*, 1993). Internalization mediated by penetratin occurs at both 37°C and 4°C, and the internalized peptide can be retrieved intact from cells.

[0242] Peptides were designed containing penetratin sequences fused to the sequences of motifs found to bind $\beta 3$ or $\beta 5$ cytoplasmic domains. The peptides were synthesized on a 431 Applied Biosystems peptide synthesizer using p-hydroxymethylphenoxymethyl polystyrene (HMP) resin and standard Fmoc chemistry. Peptide internalization and visualization was performed as described (Derossi *et al.*, 1994; Hall *et al.*, 1996; Theodore *et al.*, 1995).

[0243] Briefly, 10–50 $\mu\text{g/ml}$ of the biotinylated peptide was added to cells in culture. Peptides were incubated with plated cells. After 2–4 hours, the cultures were washed three times with tissue culture media, fixed and permeabilized using ethanol:acetic acid (9:1) for 5 min at -20°C . Nonspecific protein binding sites were blocked by incubating the cultures for 30 min with Tris-buffered saline (TBS) containing 10% fetal calf serum (FCS) and 0.02% Tween. The cultures were incubated in the same buffer containing FITC-conjugated Streptavidin (1:200 dilution) and washed with TBS before being mounted for viewing by confocal microscopy. The penetratin-linked peptides were internalized quite efficiently (data not shown).

[0244] Functional data showed that the cytoplasmic domain-binding peptides selected on $\beta 3$ or $\beta 5$ can interfere with integrin-mediated signaling and subsequent cellular responses (i.e., endothelial cell adhesion, spreading, proliferation, migration). A commercial panel of “internalizable” versions of the synthetic motifs found by phage screenings (SDNRYIGSW (SEQ ID NO:31); CEQRQTQEGC (SEQ ID NO:27); $\beta 3$ binding peptides and VVISYSMPD (SEQ ID NO:46); a $\beta 5$ -binding peptide) were obtained. These complex chimeric peptides consist of the most selective of the $\beta 3$ or $\beta 5$ -cytoplasmic domain-binding peptides coupled to penetratin, plus a biotin moiety to allow the peptides to be tracked once they were internalized into intact cells. These membrane-permeable forms of the peptides are internalized, may affect $\beta 3$ and $\beta 5$ post-ligand binding cellular events and can induce massive apoptosis (data not shown).

Endothelial cell proliferation, chemotaxis and apoptosis

[0245] The effect of $\beta 3$ and $\beta 5$ integrin cytoplasmic domain-binding motifs on endothelial cell proliferation was evaluated after stimulation with factors that activate endothelial cells (FIG. 24). Cell proliferation was measured according to Pasqualini and Hemler (1994). Briefly, 4×10^4 HUVECs were incubated in 24-well plates and starved for 24 h, after which the medium was removed and replaced in the presence of VEGF and 15 μM of each peptide. After another 18 h of incubation, 50 μl of medium containing [^3H]thymidine (1 $\mu\text{Ci}/\text{ml}$) was added to the wells. After 6 additional hours of incubation at 37°C, the medium was removed and the cells were fixed in 10% TCA for 30 min at 4°C, washed with ethanol and solubilized in 0.5 N NaOH. Radioactivity was counted by liquid scintillation by using a LS 6000SC Beckman scintillation counter. Each experiment was performed three times with triplicates, and the results were expressed as the mean \pm SD.

[0246] The effect of $\beta 3$ and $\beta 5$ integrin cytoplasmic domain-binding motifs in endothelial cell migration was evaluated after stimulation with factors that activate endothelial cells. The peptides tested affected cell function in a dose-dependent and specific way. Their properties seem to be intrinsic to the $\beta 3$ or to the $\beta 5$ cytoplasmic domain (FIG. 25).

Chemotaxis Assay.

[0247] Cell migration was assayed in a 48-well microchemotaxis chamber. Polyvinylpyrrolidone-free polycarbonate filters with 8- μm pores were coated with 1% gelatin for 10 min at room temperature and equilibrated in M199 medium supplemented with 2% FCS. Peptides were placed in the lower compartment of a Boyden chamber in M199 supplemented with 2% FCS, 20 ng/ml VEGF-A (R&D System), and 1 U/ml heparin. Overnight-starved subconfluent cultures were quickly trypsinized, and resuspended in M199 containing 2% FCS at a final concentration of 2×10^6 cells/ml. After the filter was placed between lower and upper chambers, 50 μl of the cell suspension was seeded in the upper compartment. Cells were allowed to migrate for 5 h at 37°C in a humidified atmosphere with 5% CO_2 . The filter was then removed, and cells on the upper side were scraped with a rubber policeman. Migrated cells were fixed in methanol and stained with Giemsa solution. Five random high-power fields

(magnitude 40×) were counted in each well. The results showed that both $\beta 3$ -integrin cytoplasmic domain binding peptides increased cell migration but penetratin did not affect the cells (data not shown).

Apoptosis assay (Propidium Iodide (PI) staining subdiploid population).

[0248] Approximately 1×10^6 cells were harvested in complete medium, and 15 μM of peptide was added for 4, 8, or 12 hours. The cells were then washed in PBS and resuspended in 0.5 ml propidium iodide solution (50 $\mu\text{g/ml}$ PI, 0.1% Triton X-100, 0.1% sodium citrate). After a 24-h incubation at 4°C, the cells were counted with an XL Coulter (Coulter Corporation) with a 488 nm laser; 12,000 cells were counted for each histogram, and cell cycle distributions were analyzed with the Multicycle program.

[0249] Treatment of cells with VISY-penetratin chimera resulted in induction of apoptosis (FIG. 26, panel d). Pro-apoptotic effects were not observed when the cells were exposed to other growth factors (not shown). Penetratin alone and the other penetratin chimeras also could not induce similar effects (FIG. 26, panel c). This finding shows that novel approaches for inhibiting angiogenesis can be developed based on the use of integrin targeting peptides.

Immunization with cytoplasmic domain binding peptides and characterization of the resulting antibodies

[0250] Polyclonal antibodies that recognize $\alpha v\beta 3$ and $\alpha v\beta 5$ -binding peptides were generated using KLH conjugates made with the synthetic peptides, according to standard techniques. Antibodies against two different synthetic peptides have been produced (FIG. 27). The sera not only recognize the immobilized peptides, but also recognize specific proteins in total cell extracts, as shown by western blot analysis (FIG. 28).

[0251] Rabbits were immunized with SDNRYIGSW (SEQ ID NO:31) or GLDITYRGSP (SEQ ID NO:30)-KLH conjugates. Each rabbit was injected with 200 μg of peptide conjugated with KLH in Complete Freund's Adjuvant. Between 20 and 60 days later, the rabbits were injected with 100 μg Incomplete Freund's Adjuvant. After the third immunization, sera was collected. Pre-immune serum obtained before the first immunization was used as an additional control in the experiments.

[0252] The polyclonal antibodies were tested by ELISA, Western blot and immunoprecipitation. In the ELISA assays, microtiter well plates were coated with 10 μ g/ml of peptides. The plates were dried at 37°C, blocked with PBS+3% BSA, and incubated with different serum dilutions in PBS+1% BSA. After washing and incubation with the secondary antibody, an alkaline phosphate substrate was added and antibody binding detected colorimetrically at 405 nm. The reactivity observed both in the mouse and rabbit polyclonal sera was highly specific. In all cases, antibody binding could be abrogated by preincubation with the corresponding peptide that was used for immunization, but not by a control peptide (FIG. 27 and FIG. 28). Antibodies raised against two of the β 3 cytoplasmic domain binding peptides recognize specific bands on total cell extracts and in immunoprecipitation experiments using 35S-labeled extracts. Similar results were obtained with polyclonal sera and purified IgGs (not shown).

[0253] The present example shows that targeting peptides against specific domains of cell receptors can be identified by phage display. Such peptides may be used to identify the endogenous ligands for cell receptors, such as endostatin. In addition, the peptides themselves may have therapeutic effects, or may serve as the basis for identification of more effective therapeutic agents. The endostatin targeting peptides identified herein, when introduced into cells, showed effects on cell proliferation, chemotaxis and apoptosis. The skilled artisan will realize that the present invention is not limited to the disclosed peptides or therapeutic effects. Other cell receptors and ligands, as well as inhibitors or activators thereof, may be identified by the disclosed methods.

Example 7. Induction of Apoptosis with Integrin Binding Peptides (Endothanos)

[0254] Example 6 showed that the VISY peptide (VVISYSMPD, SEQ ID NO:46), imported into cells by attachment to penetratin, could induce apoptosis in HUVEC cells. Antibodies raised against the VISY peptide were used to identify the endogenous cell analog of the peptide, identified herein as Annexin V. The results indicate that Annexin V is an endogenous ligand for the integrins that is involved in a novel pathway for apoptosis.

Methods

Protein purification

[0255] Polyclonal antibodies against the VISY peptide (VVISYSMPD, SEQ ID NO:46) were prepared using the methods described in Example 6. MDA-MB-435 breast carcinoma cells were used for purification of the endogenous VISY peptide analog. Cells were washed three times with ice cold PBS and lysed with chilled water for 20 min. Cell extracts were centrifuged for 30 min at 100,000 x g to separate the cytoplasmic fraction from the membrane fraction. The cytoplasmic fraction was subjected to column chromatography on a gel filtration column (10-50kDa) and an anion exchange column (mono Q). The anion exchange column was eluted with a salt gradient from 50 mM to 1 M NaCl. One ml fractions were collected, run on SDS-PAGE and tested by Western blotting for the presence of endogenous proteins reactive with the anti-VISY antibody. The fraction of interest, containing a 36 kDa antibody reactive band, eluted at about 300 mM NaCl.

[0256] The 36 kDa always appeared in fractions that showed positive reactivity with the anti-VISY antibody. The fractions were analyzed by SDS-PAGE and 2-D gel electrophoresis, followed by Western blotting. A substantial enrichment of the 36 kDa protein was seen after column chromatography (not shown). The 36 kDa peptide was cut from the SDS-PAGE gel and analyzed by mass spectroscopy to obtain its sequence. All five peptide sequences that were obtained by mass spectroscopy showed 100% homology to the reported sequence of Annexin V (GenBank Accession No. GI_468888). In addition to its presence in 435 cells, the 36 kDa band was also seen in Kaposi sarcoma, SKOV and HUVEC cells (not shown).

[0257] Commercial antibodies against Annexin V were obtained (Santa Cruz Biologics, Santa Cruz, CA). Comparative Western blots were performed using the anti-VISY antibody and the anti-Annexin V antibody. Both antibodies showed reactivity with the 36 kDa protein (not shown). These results indicate that the endogenous protein analog of the VISY peptide is Annexin V.

Protein-protein interaction with Annexin V and $\beta 5$ cytoplasmic domain.

[0258] Competitive binding assays were performed to examine the binding of Annexin V to $\beta 5$ integrin and the effect of the VISY peptide. Plates were coated with GST fusion proteins of the cytoplasmic domains of various integrins and Annexin V was added to the plates. Binding of Annexin V was determined using anti-Annexin V

antibodies. As shown in FIG. 29A, Annexin V did not bind to either the GST- β 1 or GST- β 3 integrins. Annexin V bound strongly to the GST- β 5 integrin, but binding was dependent on the buffer used (FIG. 29A). Low binding was observed in Tris-buffered saline (TBS), while high binding was observed in "cytoplasmic buffer" (100 mM KCl, 3 mM NaCl, 3.5 mM $MgCl_2$, 10 mM PIPES, 3 mM DTT) with or without added calcium (2 mM) (FIG. 29A). Calcium was used because Annexin V activity has been reported to be modulated by calcium. Binding of Annexin V to GST- β 5 was blocked by addition of the VISY peptide (FIG. 29A). FIG. 29B shows the relative levels of binding of anti-Annexin V antibody to purified Annexin V and to VISY peptide.

[0259] A reciprocal study was performed, using Annexin V to coat plates and adding GST fusion proteins of integrin cytoplasmic domains. Binding was assessed using anti-GST fusion protein antibodies. As expected, only GST- β 5 showed substantial binding to Annexin V, while GST- β 1 and GST- β 3 showed low levels of Annexin V binding (not shown). In some studies, calcium ion appeared to interfere with the binding interaction between GST- β 5 and Annexin V, with decreased binding observed in the presence of calcium (not shown). A greater degree of inhibition of Annexin V binding to GST- β 5 by the VISY peptide was observed in the presence of calcium (67% inhibition) than in the absence of calcium (45%) (FIG. 29A).

Penetratin peptide chimera binding to the $\beta 5$ cytoplasmic domain induces programmed cell death.

[0260] The induction of apoptosis by VISY peptide was shown in Example 6 was confirmed. 10^6 HUVEC were treated with $15 \mu\text{M}$ of VISY antennapedia (penetratin) chimera or $15 \mu\text{M}$ of antennapedia peptide (penetratin) alone for 2-4 hours and chromatin fragmentation was analyzed by electrophoresis in an agarose gel. FIG. 30 shows the induction of apoptosis by VISY-Ant (penetratin), as indicated by chromatin fragmentation. Neither VISY nor penetratin alone induced apoptosis. Induction of apoptosis was inhibited up to 70% when a caspase inhibitor (zVAD, caspase inhibitor I, Calbiochem #627610, San Diego, CA) was added to the media at the same time as the VISY chimeric peptide.

[0261] A distinction between the mechanism of cell death induced by VISY peptide and other pro-apoptosis agents is that other apoptotic mechanisms evaluated in cell culture typically involve detachment of the cells from the substrate, followed by cell death. In contrast, in VISY induced cell death, the cells do not detach from the substrate before dying. Thus, endothanos (death from inside) appears to differ from anoikis (homelessness).

[0262] The present results show that VISY peptides activate an integrin dependent apoptosis pathway. The present example shows that the endogenous analog for VISY peptide is Annexin V. These results demonstrate the existence of a novel apoptotic pathway, mediated through an interaction between Annexin V and $\beta 5$ integrin and dependent on caspase activity. This novel apoptotic mechanism is termed endothanos. The skilled artisan will realize that the existence of a novel mechanism for inducing or inhibiting apoptosis is of use for a variety of applications, such as cancer therapy.

Example 8. Identification of Receptor/Ligand Pairs: Aminopeptidase A regulates endothelial cell function and angiogenesis

[0263] Endothelial cells in tumor vessels express specific angiogenic markers. Aminopeptidase A (APA, EC 3.4.11.7) is upregulated in microvessels undergoing angiogenesis. APA is a homodimeric, membrane-bound zinc metallopeptidase that hydrolyzes N-terminal glutamyl or aspartyl residues from oligopeptides (Nanus *et al.*, 1993). *In vivo*, APA converts angiotensin II to angiotensin III. The renin-angiotensin

system plays an important role in regulating several endocrine, cardiovascular, and behavioral functions (Ardailou, 1997; Stroth and Unger, 1999). Recent studies also suggest a role for angiotensins in angiogenesis (Andrade *et al.*, 1996), but the function of APA in the angiogenic process has not been investigated so far.

[0264] In the present example, targeting peptides capable of binding APA were identified by screening phage libraries on APA-expressing cells. APA-binding peptides containing the motif CPRCESIC (SEQ ID NO:56) specifically inhibited APA enzyme activity. Soluble CPRCESIC (SEQ ID NO:56) peptide inhibited migration, proliferation, and morphogenesis of endothelial cells *in vitro* and interfered with *in vivo* angiogenesis in a chick embryo chorioallantoic membrane (CAM) assay. Furthermore, APA null mice had a decreased amount of retinal neovascularization compared to wild type (wt) mice in hypoxia-induced retinopathy in premature mice. These results may lead to a better understanding of the role of APA in angiogenesis and to development of new anti-tumor therapeutic strategies.

Materials and Methods

Cell cultures

[0265] The renal carcinoma cell line SK-RC-49 was transfected with an expression vector encoding full-length APA cDNA (Geng *et al.*, 1998). Cells were maintained in MEM (Irvine Scientific, Santa Ana, CA), supplemented with 2 mM glutamine, 1% nonessential amino acids, 1% vitamins (Gibco BRL), 100 U/ml streptomycin, 100 U/ml penicillin (Irvine Scientific), 10 mM sodium pyruvate (Sigma-Aldrich), and 10% fetal calf serum (FCS) (Tissue Culture Biological, Tulare, CA). Stably transfected cells were maintained in G418-containing medium. HUVECs were isolated by collagenase treatment and used between passages 1 to 4. Cells were grown on gelatin-coated plastic in M199 medium (Sigma) supplemented with 20% FCS, penicillin (100 U/ml), streptomycin (50 µg/ml), heparin (50 µg/ml), and bovine brain extract (100 µg/ml). All media supplements were obtained commercially (Life Technologies, Inc., Milan, Italy).

Antibodies and peptides

[0266] The anti-APA mAb RC38 (Schlingemann *et al.*, 1996) was used to immunocapture APA from transfected cell lysates. CPRCESIC (SEQ ID NO:56) and

GACVRLSACGA (SEQ ID NO:57) cyclic peptides were chemically synthesized, spontaneously cyclized in non-reducing conditions, and purified by mass spectrometry (AnaSpec San Jose, CA). The mass spectrometer analysis of the CPRECSIC (SEQ ID NO:56) peptide revealed six different peaks, possibly reflecting different positions of disulfide bounds and the formation of dimers. Due to the similar biochemical behavior of the different fractions on APA enzyme activity, a mix of the six peaks was used in all procedures described below.

APA immunocapture

[0267] Cells were scraped from semi-confluent plates in cold PBS containing 100 mM N-octyl- β -glucopyranoside (Calbiochem), lysed on ice for 2 h, and centrifuged at 13,000 $\times g$ for 15 min. Microtiter round-bottom wells (Falcon) were coated with 2 μ g of RC38 for 4 h at room temperature and blocked with PBS/3% BSA (InterGen, Purchase, NY) for 1 h at room temperature, after which 150 μ l of cell lysate (1 mg/ml) was incubated on the mAb-coated wells overnight at 4°C, washed five times with PBS/0.1% Tween-20 (Sigma), and washed twice with PBS.

APA enzyme assay

[0268] Cells and immunocaptured proteins were tested for specific enzyme activity according to Liln *et al.* (1998). Briefly, adherent cells or RC38-immunocaptured cell extracts were incubated for 2 h at 37°C with PBS containing 3 mM α -L-glutamyl-p-nitroanilide (Fluka) and 1 mM CaCl_2 . Enzyme activity was determined by reading the optical absorbance (O.D.) at 405 nm in a microplate reader (Molecular Devices, Sunnyvale, CA).

Cell panning

[0269] A $\text{CX}_2\text{CX}_3\text{CX}_2\text{C}$ (C, cysteine; X, any amino acid) library was prepared (Rajotte *et al.*, 1998). Amplification and purification of phage particles and DNA sequencing of phage-displayed inserts were performed as described. Cells were detached by incubation with 2.5 mM EDTA in PBS, washed once in binding medium (DMEM high glucose supplemented with 20 mM HEPES and 2% FCS), and resuspended in the same medium at a concentration of 2×10^6 cells/ml. 10^{10} TU of phage were added to 500 μ l of the cell suspension, and the mixture was incubated overnight (first round) or for 2 h

(successive rounds) at 4°C with gentle rotation. Cells were washed five times in binding medium at room temperature and resuspended in 100 µl of the same medium. Phage were rescued by adding 1 ml of exponentially growing K91Kan *Escherichia coli* bacteria and incubating the mixture for 1 h at room temperature. Bacteria were diluted in 10 ml of LB medium supplemented with 0.2 µg/ml tetracycline and incubated for another 20 min at room temperature. Serial dilutions were plated on LB plates containing 40 µg/ml tetracycline, and plates were incubated at 37°C overnight before colonies were counted.

Phage binding specificity assay

[0270] The cell binding assay was performed with an input of 10^9 TU as described for the cell panning. The specificity was confirmed by adding CPRECESIC (SEQ ID NO:56) peptide to the binding medium in increasing concentrations. For phage binding on immunocaptured APA, wells were blocked for 1 h at room temperature with PBS/3% BSA and incubated with 10^9 TU for 1 h at room temperature in 50 µl PBS/3% BSA. After eight washes in PBS/1% BSA/0.01% Tween-20 and two washes in PBS, phage were rescued by adding 200 µl of exponentially growing K91Kan *E. coli*. Each experiment was repeated at least three times.

In vivo tumor homing of APA-binding phage

[0271] MDA-MB-435-derived tumor xenografts were established in female nude mice 2 months old (Jackson Labs, Bar Harbor, Maine). Mice were anesthetized with Avertin and injected intravenously through the tail vein with 10^9 TU of the phage in a 200 µl volume of DMEM. The phage were allowed to circulate for 5 min, and the animals were perfused through the heart with 5 ml of DMEM. The tumor and brain were dissected from each mouse, weighed, and equal amounts of tissue were homogenized. The tissue homogenates were washed three times with ice-cold DMEM containing a proteinase inhibitor cocktail and 0.1% BSA. Bound phage were rescued and counted as described for cell panning. Fd-tet phage was injected at the same input as a control. The experiment was repeated twice. In parallel, part of the same tissue samples were fixed in Bouin solution, and imbedded in paraffin for preparation of tissue sections. An antibody to M-13 phage (Amersham-Pharmacia) was used for the staining.

Cell growth assay

[0272] HUVECs were seeded in 48-well plates (10^4 cells/well) and allowed to attach for 24 h in complete M199 medium. The cells were then starved in M199 medium containing 2% FCS for 24 h. CPRECECIS (SEQ ID NO:56) or control GACVRLSACGA (SEQ ID NO:57) peptide (1 mM) was added to the wells in medium containing 2% FCS and 10 ng/ml VEGF-A (R&D System, Abingdom, UK). After incubation for the indicated times, cells were fixed in 2.5% glutaraldehyde, stained with 0.1% crystal violet in 20% methanol, and solubilized in 10% acetic acid. All treatments were done in triplicate. Cell growth was evaluated by measuring the O.D. at 590 nm in a microplate reader (Bio-Rad Laboratories, Hercules, CA). A calibration curve was established and a linear correlation between O.D. and cell counts was observed between 10^3 and 10^5 cells.

Chemotaxis assay

[0273] A cell migration assay was performed in a 48-well microchemotaxis chamber (NeuroProbe, Gaithersburg, MD) according to Bussolini *et al.* (1995). Polyvinylpyrrolidone-free polycarbonate filters (Nucleopore, Cambridge, MA) with 8- μ m pores were coated with 1% gelatin for 10 min at room temperature and equilibrated in M199 medium supplemented with 2% FCS. CPRECECIS (SEQ ID NO:56) or control GACVRLSACGA (SEQ ID NO:57) peptide (1 mM) was placed in the lower compartment of a Boyden chamber in M199 medium supplemented with 2% FCS and 10 ng/ml VEGF-A (R&D System). Subconfluent cultures that had been starved overnight were harvested in PBS containing 2.5 mM EDTA, washed once in PBS, and resuspended in M199 medium containing 2% FCS at a final concentration of 2×10^6 cells/ml. After the filter was placed between the lower and upper chambers, 50 μ l of the cell suspension was seeded in the upper compartment, and cells were allowed to migrate for 5 h at 37°C in a humidified atmosphere with 5% CO₂. The filter was then removed, and cells on the upper side were scraped with a rubber policeman. Migrated cells were fixed in methanol and stained with Giemsa solution (Diff-Quick, Baxter Diagnostics, Rome, Italy). Five random high-power fields (magnitude 100 \times) were counted in each well. Each assay was run in triplicate.

Three-dimensional cell culture

[0274] Matrigel (Collaborative Research, Bedford, MA) was added at 100 μ l per well to 48-well tissue culture plates and allowed to solidify for 10 min at 37°C. HUVECs were starved for 24 h in M199 medium supplemented with 2% FCS before being harvested in PBS containing 2.5 mM EDTA. 10^4 cells were gently added to each of the triplicate wells and allowed to adhere to the gel coating for 30 min at 37°C. Then, medium was replaced with indicated concentrations of CPRECESIC (SEQ ID NO:56) or GACVRLSACGA (SEQ ID NO:57) peptides in complete medium. The plates were photographed after 24 h with an inverted microscope (Canon). The assay was repeated three times.

CAM assay

[0275] *In vivo* angiogenesis was evaluated by a CAM assay (Ribatti *et al.*, 1994). Fertilized eggs from White Leghorn chickens were maintained in constant humidity at 37°C. On the third day of incubation, a square window was opened in the eggshell and 2–3 ml of albumen was removed to detach the developing CAM from the shell. The window was sealed with a glass plate of the same size and the eggs were returned to the incubator. At day 8, 1 mm³ sterilized gelatin sponges (Gelfoam, Upjohn Co, Kalamazoo, Milan) were adsorbed with VEGF-A (20 ng, R&D System) and either CPRECESIC (SEQ ID NO:56) or control GACVRLSACGA (SEQ ID NO:57) peptide (1 mM) in 3 μ l PBS and implanted on the top of the growing CAMs under sterile conditions. CAMs were examined daily until day 12 and photographed *in ovo* with a Leica stereomicroscope. Capillaries emerging from the sponge were counted. The assay was repeated twice.

Induction of retinal neovascularization

[0276] APA null mice have been described (Lin *et al.*, 1998). Mice pups on P7 (7th day postpartum) with their nursing mothers were exposed to 75% oxygen for 5 days. Mice were brought back to normal oxygen (room air) on P12. For histological analysis mice were killed between P17 and P21 and eyes were enucleated and fixed in 4% paraformaldehyde in PBS overnight at 4°C. Fixed eyes were imbedded in paraffin and 5 μ m serial sections were cut. Sections were stained with hematoxylin/eosin solution. Neovascular nuclei on the vitreous side of the internal limiting membrane were counted

from 20 h/e-stained sections per each eye. The average number of neovascular nuclei per section was calculated and compared between animal groups using Student's t-test.

Results

Cell panning with phage display select an APA-binding motif

[0277] To identify a peptide capable of binding to APA, cells were screened with a random peptide phage library. First, SK-RC-49 renal carcinoma cells, which do not express APA, were transfected with full-length APA cDNA to obtain a model of APA expression in the native conformation. APA expressed as a result of transfection was functionally active, as evidenced by an APA enzyme assay (not shown), but parental SK-RC-49 cells showed neither APA expression nor activity (not shown).

[0278] The CX₃CX₃CX₃C phage library (10¹⁰ transducing units [TU]) was preadsorbed on parental SK-RC-49 cells to decrease nonspecific binding. Resuspended SK-RC-49/APA cells were screened with phage that did not bind to the parent cells. SK-RC-49/APA-bound phage were amplified and used for two consecutive rounds of selection. An increase in phage binding to SK-RC-49/APA cells relative to phage binding to SK-RC-49 parental cells was observed in the second and third rounds (not shown).

[0279] Subsequent sequencing of the phage revealed a specific enrichment of a peptide insert, CYNLCIRECESICGADGACWTWCADGCSRSC (SEQ ID NO:58), with a tandem repetition of the general library sequence CX₃CX₃CX₃C. This sequence represented 50% of 18 randomly selected phage inserts from round 2 and 100% of phage inserts from round 3. Four peptide inserts derived from round 2 shared sequence similarity with the tandem phage (Table 7, in bold font). Several other apparently conserved motifs were observed among round 2 peptides (Table 7, underlined or italicized). One of these overlapped in part with the tandem repeated sequence. A search for sequence homology of the selected peptides against human databases did not yield a significant match.

Table 7. APA-binding peptide sequences.

Peptide sequences	Round 2 (%) / 3 (%)
CYNLCIRECESICGADGACWTWCADGCSRSC (SEQ ID NO:58)	50/100
CLGQCASICVNDC (SEQ ID NO:59)	5/-
CPKVCPRECESNC (SEQ ID NO:60)	5/-
CGTGCAVECEVVC (SEQ ID NO:61)	5/-
CAVACWADCQLGC (SEQ ID NO:62)	5/-
CSGLCTVQCLEGC (SEQ ID NO:63)	5/-
CSMMCLEGCDDWC (SEQ ID NO:64)	5/-
OTHER	20/-

Selected phage inserts are specific APA ligands.

[0280] Phage displaying the peptide inserts CYNLCIRECESICGADGACWTWCADGCSRSC (SEQ ID NO:58), CPKVCPRECESNC (SEQ ID NO:60) or CLGQCASICVNDC (SEQ ID NO:59) were individually tested for APA binding. All three phage specifically bound to the surface of SK-RC-49/APA cells (not shown), with a similar pattern of 6-fold enrichment relative to SK-RC-49 parental cells. Control, insertless phage showed no binding preference (not shown). CGTGCAVECEVVC (SEQ ID NO:61) and the other phage selected in round 2 showed no selective binding to SK-RC-49/APA cells (data not shown). A soluble peptide, CPRECESIC (SEQ ID NO:56) containing a consensus sequence reproducing the APA-binding phage inserts was synthesized.

[0281] Binding assays were performed with CPKVCPRECESNC (SEQ ID NO:60) phage in the presence of the CPRECESIC (SEQ ID NO:56) peptide. Soluble CPRECESIC (SEQ ID NO:56) peptide competed with CPKVCPRECESNC (SEQ ID NO:60) phage for binding to SK-RC-49/APA cells, but had no effect on nonspecific

binding to SK-RC-49 parental cells (not shown). The unrelated cyclic peptide GACVRLSACGA (SEQ ID NO:57) had no competitive activity (not shown). Binding of CYNLCIRECESICGADGACWTWCADGCSRSC (SEQ ID NO:58) phage was also displaced by CPRECESIC (SEQ ID NO:56) peptide, but the binding of CLGQCASICVNDC (SEQ ID NO:59) phage was not affected (data not shown).

[0282] To further confirm the substrate specificity of the selected peptide inserts, APA was partially purified from APA-transfected cell extracts by immunocapture with mAb RC38. The APA protein immobilized on RC38-coated microwells was functional, as confirmed by enzyme assay (not shown). The CYNLCIRECESICGADGACWTWCADGCSRSC (SEQ ID NO:58), CPKVCPRECESNC (SEQ ID NO:60), and CLGQCASICVNDC (SEQ ID NO:59) phage selectively bound immunocaptured APA, with a 10- to 12-fold enrichment compared to phage binding to RC38-immunocaptured cell lysates from SK-RC-49 parental cells (not shown).

APA-binding phage target tumors in vivo.

[0283] The ability of the identified peptide to home to tumors was evaluated, using nude mice implanted with human breast tumor xenografts as a model system. Phage were injected into the tail vein of tumor-bearing mice, and targeting was evaluated by phage recovery from tissue homogenates. CPKVCPRECESNC (SEQ ID NO:60) phage was enriched 4-fold in tumor xenografts compared to brain tissue, which was used as a control (FIG. 31). Insertless phage did not target the tumors (FIG. 31). Neither CYNLCIRECESICGADGACWTWCADGCSRSC (SEQ ID NO:58) nor CLGQCASICVNDC (SEQ ID NO:59) phage showed any tumor-homing preference (data not shown).

[0284] The homing of CPKVCPRECESNC (SEQ ID NO:60) was confirmed by anti-M13 immunostaining on tissue sections (not shown). Strong phage staining was apparent in tumor vasculature but not in normal vasculature (not shown). Insertless phage did not bind to tumor vessels.

CPRECESIC (SEQ ID NO:56) is a specific inhibitor of APA activity.

[0285] To investigate the effect of CPRECESIC (SEQ ID NO:56) on APA enzyme activity, SK-RC-49/APA cells were incubated with the APA specific substrate α -glutamyl-p-nitroanilide in the presence of increasing concentrations of either CPRECESIC (SEQ ID NO:56) or control GACVRLSACGA (SEQ ID NO:57) peptides. Enzyme activity was evaluated by a colorimetric assay after 2 h incubation at 37°C. CPRECESIC (SEQ ID NO:56) inhibited APA enzyme activity, reducing the activity by 60% at the highest concentration tested (FIG. 32). The IC_{50} of CPRECESIC (SEQ ID NO:56) for enzyme inhibition was calculated to be 800 μ M. CPRECESIC (SEQ ID NO:56) did not affect the activity of a closely related protease, aminopeptidase N (data not shown).

CPRECESIC (SEQ ID NO:56) inhibits migration and proliferation of endothelial cells.

[0286] The potential use of CPRECESIC (SEQ ID NO:56) peptide as an anti-angiogenic drug was determined. First, the effect of APA inhibition by CPRECESIC (SEQ ID NO:56) peptide *in vitro* on the migration and proliferation of human umbilical vein endothelial cells (HUVECs) stimulated with VEGF-A (10 ng/ml) was examined. The presence of functional APA on HUVECs was evaluated by enzyme assay (not shown). At the highest concentration tested (1 mM), CPRECESIC (SEQ ID NO:56) peptide inhibited chemotaxis of HUVECs by 70% in a Boyden chamber assay (FIG. 33). At the same peptide concentration, cell proliferation was inhibited by 50% (FIG. 34). Lower concentrations of CPRECESIC (SEQ ID NO:56) peptide or the GACVRLSACGA (SEQ ID NO:57) control peptide had no significant effect on cell migration or proliferation (not shown).

CPRECESIC (SEQ ID NO:56) inhibits angiogenesis in vitro and in vivo

[0287] The inhibitory effect of CPRECESIC (SEQ ID NO:56) peptide in different *in vitro* and *in vivo* models of angiogenesis was examined. HUVECs plated on a three-dimensional matrix gel differentiate into a capillary-like structure, providing an *in vitro* model for angiogenesis. Increasing concentrations of CPRECESIC (SEQ ID NO:56) peptide resulted in a progressive impairment of the formation of this network (not shown). At a peptide concentration of 1 mM, vessel-like branching structures were significantly fewer and shorter, and as a result, the cells could not form a complete

network organization (not shown). The control peptide GACVRLSACGA (SEQ ID NO:57) did not affect HUVEC morphogenesis (not shown).

[0288] A commonly used model of simplified *in vivo* angiogenesis is the chicken chorioallantoic membrane (CAM), in which neovascularization can be stimulated during embryonic development. An appropriate stimulus, adsorbed on a gelatin sponge, induces microvessel recruitment to the sponge itself, accompanied by remodeling and ramification of the new capillaries. Eight-day-old chicken egg CAMs were stimulated with VEGF-A alone (20 ng) or with VEGF-A plus CPRECESIC (SEQ ID NO:56) or GACVRLSACGA (SEQ ID NO:57) (1 mM) peptides. The CAMs were photographed at day 12. Neovascularization induced by VEGF-A was inhibited by CPRECESIC (SEQ ID NO:56) by 40% based on the number of capillaries emerging from the sponge (Table 8). The neovessels did not show the highly branching capillary structures typically seen after VEGF-A stimulation (not shown). Treatment with control peptide GACVRLSACGA (SEQ ID NO:57) or with lower peptide concentrations of CPRECESIC (SEQ ID NO:56) had no effect on the number of growing vessels (not shown).

Table 8. CAM assay for angiogenesis

TREATMENT	BLOOD VESSEL NUMBERS
No VEGF-A	12.0 ± 2.82*
VEGF-A	57.0 ± 1.41*
VEGF-A + control	56.5 ± 2.12
VEGF-A + CPRECESIC (SEQ ID NO:56)	5.5 ± 1.41*

APA-deficient mice show impaired neovascularization

[0289] The ability of APA^{+/+} and APA^{-/-} null mice to undergo neovascularization was examined in a model of hypoxic retinopathy in premature mice. Induction of retinal

neovascularization by relative hypoxia was already present in APA^{+/+} mice compared to wild type mice (not shown). Neovascularization was almost undetectable in APA null mice (not shown). Neovascularization was quantified by counting vitreous protruding neovascular nuclei from 20 sections of hypoxic eyes. Significant induction of retinal neovascularization (16.17 ± 1.19 neovascular nuclei/eye section) was seen in the wild type mice on postnatal day 17 (P17) after 75% oxygen treatment from P7 to P12. Decreased amounts of neovascular nuclei were seen in the retinas of APA^{+/+} (10.76 ± 1.03 neovascular nuclei/eye section) and APA null (4.25 ± 0.45 neovascular nuclei/eye section) mice on P17 after exposure to 75% oxygen from P7 to P12.

Discussion

[0290] *In vivo*, APA is overexpressed by activated microvessels, including those in tumors, but it is barely detectable in quiescent vasculature, making it a suitable target for vessel-directed tumor therapy. The present example identified a novel targeting peptide ligand for APA, CPRECESIC (SEQ ID NO:56). Soluble CPRECESIC (SEQ ID NO:56) peptide inhibited APA enzyme activity with an IC₅₀ of 800 μ M.

[0291] Using cultured HUVECs as an *in vitro* model of angiogenesis, soluble CPRECESIC (SEQ ID NO:56) peptide inhibited VEGF-A-induced migration and proliferation of HUVECs. These data are consistent with a requirement for migration and proliferation of endothelial cells during angiogenesis. CPRECESIC (SEQ ID NO:56) also blocked the formation of capillary-like structures in a Matrigel model and inhibited angiogenesis in VEGF-A-stimulated CAMs.

[0292] APA was shown to be an important player in neovascularization induced by relative hypoxia, since APA null mice had significantly less retinal neovascularization compared to wt mice. These results strengthen the potential of using APA as a specific target for the inhibition of tumor angiogenesis.

[0293] In summary, the soluble peptide CPRECESIC (SEQ ID NO:56) is a selective APA ligand and inhibitor. The inhibition of APA by CPRECESIC (SEQ ID NO:56) led to the inhibition of angiogenesis in different *in vitro* and *in vivo* assays, demonstrating for the first time a prominent role for APA in the angiogenic process. Furthermore, APA-binding phage can home to tumor blood vessels, suggesting possible therapeutic

uses of CPRECESIC (SEQ ID NO:56) as an inhibitor of tumor neovascularization. The endogenous analog of CPRECESIC (SEQ ID NO:56) may be identified by antibody based purification or identification methods, similar to those disclosed.

Example 9. Screening Phage Libraries by PALM

[0294] In certain embodiments, it is desirable to be able to select specific cell types from a heterogeneous sample of an organ or tissue. One method to accomplish such selective sampling is by PALM (Positioning and Ablation with Laser Microbeams).

[0295] The PALM Robot-Microbeam uses a precise, computer-guided laser for microablation. A pulsed ultra-violet (UV) laser is interfaced into a microscope and focused through an objective to a beam spot size of less than 1 micrometer in diameter. The principle of laser cutting is a locally restricted ablative photodecomposition process without heating (Hendrix, 1999). The effective laser energy is concentrated on the minute focal spot only and most biological objects are transparent for the applied laser wavelength. This system appears to be the tool of choice for recovery of homogeneous cell populations or even single cells or subcellular structures for subsequent phage recovery. Tissue samples may be retrieved by circumcising a selected zone or a single cell after phage administration to the subject. A clear-cut gap between selected and non-selected area is typically obtained. The isolated tissue specimen can be ejected from the object plane and catapulted directly into the cap of a common micro centrifuge tube in an entirely non-contact manner. The basics of this so called Laser Pressure Catapulting (LPC) method is believed to be the laser pressure force that develops under the specimen, caused by the extremely high photon density of the precisely focused laser microbeam. This tissue harvesting technique allows the phage to survive the microdissection procedure and be rescued.

[0296] PALM was used in the present example to select targeting phage for mouse pancreatic tissue, as described below.

Materials and Methods

In vivo and in situ Panning

[0297] A CX₇C peptide phage library (10⁹ TU) was injected into the tail vein of a C57BL/6 male mouse, and the pancreas was harvested to recover the phage by bacterial infection. Phage from 246 colonies were grown separately in 5 ml LB/kanamycin (100

$\mu\text{g/ml}$ /tetracycline ($40 \mu\text{g/ml}$) at 37°C in the dark with agitation. Overnight cultures were pooled and the phage purified by NaCl/PEG precipitation for another round of *in vivo* bio-panning. Three hundred colonies were picked from the second round of panning, and the phage were recovered by precipitation. Phage from the second bio-panning round was then used for another round of *in vivo* panning and also was incubated with thawed frozen murine pancreatic sections for one *in situ* panning round.

[0298] For the third *in vivo* panning round, 10^9 TU phage from the second round were injected into a third mouse and allowed to circulate for six minutes, followed by an intravenous injection of $50 \mu\text{l}$ of FITC-lectin (Vector Laboratories, Inc.). After a two-minute circulation, the mouse was perfused through the left ventricle with 3 ml MEM Earle salts. The pancreas was harvested, frozen at -80°C in Tissue Tek (Sakura), and sectioned onto prepared slides.

[0299] For the third *in situ* round, purified phage, isolated from the second round, were incubated with $4\text{--}14 \mu\text{m}$ thawed murine pancreatic sections on ice for 30 minutes. Sections were rinsed with $100 \mu\text{l}$ ice-cold PBS 8x at room temperature (RT). Bound phage were recovered from each section by adding $100 \mu\text{l}$ K91 Kan^R ($\text{OD}_{600} = 2.03$) to infect at RT for 30-60 minutes. Infected K91 KanR were withdrawn from each section and allowed to recover in 10 ml LB/Kan/Tet ($0.2 \mu\text{g/ml}$) for 20 minutes in the dark. Aliquots from the each culture were plated out onto LB/Kan/Tet ($40 \mu\text{g/ml}$) plates and incubated overnight in the dark at 37°C . The tetracycline concentration of the remainder of each culture was increased to $40 \mu\text{g/ml}$ and the cultures were incubated overnight at 37°C in the dark with agitation for phage amplification and purification.

DNA Amplification

[0300] Phage were recovered from cryo-preserved FITC-lectin stained mouse pancreatic islets and surrounding acinar cells that were microdissected from $14 \mu\text{m}$ sections using the PALM (Positioning and Ablation with Laser Microbeams) cold laser pressure catapulting system. Pancreatic islet and control sections were catapulted into 1 mM EDTA, pH 8, and frozen at -20°C until enough material was collected for PCR amplification. Phage DNA was amplified with fUSE5 primers: forward primer 5' TAA TAC GAC TCA CTA TAG GGC AAG CTG ATA AAC CGA TAC AATT 3' (SEQ ID

NO:65), reverse primer 5' CCC TCA TAG TTA GCG TAA CGA TCT 3' (SEQ ID NO:66). The PCR products were subjected to another round of PCR using a nested set of primers. The 3' end of the second primer set was tailed with the M13 reverse primer for sequencing purposes. The nested primer set used was: forward nested primer 5' CCTTCTATTCTCACTCGGCCG 3' (SEQ ID NO:67), reverse nested primer 5' CAGGAAACAGCTATGACCGCTAAACAACCTTCAACAGITTCGGC 3' (SEQ ID NO:68). To generate peptide insert sequence containing flanking SfiI restriction sites, two more primers were used: forward library primer 5' CACTCGGCCGACGGGGC 3' (SEQ ID NO:69), reverse primer 5' CAGTTTCGGCCCCAGCGGCC 3' (SEQ ID NO:70). PCR products generated from the nested primers were gel purified (Qiagen), and confirmed for the presence of a CX₇C peptide insert sequence using the M13 reverse primer by automated sequencing. PCR products generated from the library primers were gel purified (Qiagen), ligated into CsCl₂ purified fUSE5/SfiI, electroporated into electrocompetent MC1061 cells, and plated onto LB/streptomycin (100 µg/ml)/tetracycline (40 µg/ml) agar plates. Single colonies were subjected to colony PCR using the fUSE5 primers to verify the presence of a CX₇C insert sequence by gel electrophoresis. Positive clones were sequenced using BigDye terminators (Perkin Elmer)

Phage Infection

[0301] Pancreatic islet and control sections were catapulted into 1 mM AEBSF, 20 µg/ml aprotinin, 10 µg/ml leupeptin, 1 mM elastase inhibitor I, 0.1 mM TPCK, 1 nM pepstatin A in PBS, pH 7.4, and frozen for 48 hours or less until enough material was collected. The sections were thawed on ice and the volume adjusted to 200 µl with PBS, pH 7.4. Samples were incubated with 1 ml K91 Kan^R (OD = 0.22) for two hours at RT on a nutator. Each culture was transferred to 1.2 ml LB/Kan/Tet (0.2 µg/ml) and incubated in the dark at RT for 40 minutes. The tetracycline concentration was increased to 40 µg/ml for each culture, and the cultures were incubated overnight at 37 °C with agitation. Each culture was plated out the following day onto LB/Kan/Tet agar plates and incubated for 14 hours at 37 °C in the dark. Positive clones were picked for colony PCR and automated sequencing.

Results

[0302] The general scheme for *in vivo* panning using PALM is illustrated in FIG. 35. After an initial round of *in vivo* selection, phage were either bulk amplified or else single colonies of phage from pancreas, kidney, lung and adrenal glands were amplified and subjected to additional rounds of *in vivo* screening. Both bulk amplified and colony amplified phage from mouse pancreas showed successive enrichment with increasing rounds of selection (not shown). After three rounds of selection, the colony amplified phage showed almost an order of magnitude higher enrichment than bulk amplified phage (not shown).

[0303] Table 9 lists selected targeting sequences and consensus motifs identified by pancreatic screening.

[0304] FIG. 36 shows a general protocol for recovery of phage insert sequences from PALM selected thin section materials. As indicated, phage may be recovered by direct infection of *E. coli* host bacteria, after protease digestion of the thin section sample. Alternatively, phage inserts may be recovered by PCR amplification and cloned into new vector DNA, then electroporated or otherwise transformed into host bacteria for cloning.

[0305] Both methods of PALM recovery of phage were successful in retrieving pancreatic targeting sequences. Pancreatic sequences recovered by direct bacterial infection included CVPRRWDC (SEQ ID NO:128), CQHTSGRGC (SEQ ID NO:129), CRARGWLLC (SEQ ID NO:130), CVSNPRWKC (SEQ ID NO:131), CGGVHALRC (SEQ ID NO:98), CFNRTWIGC (SEQ ID NO:132) and CSRGPAWGC (SEQ ID NO:133). Pancreatic targeting sequences recovered by amplification of phage inserts and cloning into phage include CWSRGQGGC (SEQ ID NO:134), CHVLWSTRC (SEQ ID NO:135), CLGLLMAGC (SEQ ID NO:136), CMSSPGVAC (SEQ ID NO:137), CLASGMDAC (SEQ ID NO:138), CHDERTGRC (SEQ ID NO:139), CAHHALMEC (SEQ ID NO:140), CMQGAATSC (SEQ ID NO:141), CMQGARTSC (SEQ ID NO:142) and CVRDLLTGC (SEQ ID NO:143).

[0306] FIG. 37 through FIG. 40 show sequence homologies identified for selected pancreatic targeting sequences. Several proteins known to be present in pancreatic tissues are identified. The results of this example show that the PALM method may be used for selecting cell types from tissue thin sections and recovering targeting phage sequences. The skilled artisan will realize that this method could be used with virtually

any tissue to obtain targeting sequences directed to specific types of cells in heterologous organs or tissues.

WHAT IS CLAIMED IS:

1. A method of treating obesity comprising:
 - a) obtaining a targeting peptide selective for adipose tissue;
 - b) attaching the peptide to a therapeutic agent to form a complex;
 - c) administering the complex to a subject; and
 - d) inducing weight loss in the subject.
2. The method of claim 1, wherein the targeting peptide comprises at least three contiguous amino acids of a sequence selected from SEQ ID NO:13, SEQ ID NO:14, SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:22.
3. The method of claim 2, wherein the targeting peptide has the amino acid sequence of SEQ ID NO:19 or SEQ ID NO:22
4. The method of claim 1, wherein said therapeutic agent is a drug, a chemotherapeutic agent, a radioisotope, a pro-apoptosis agent, an anti-angiogenic agent, a hormone, a cytokine, a cytotoxic agent, a cytocidal agent, a cytostatic agent, a peptide, a protein, an antibiotic, an antibody, a Fab fragment of an antibody, a hormone antagonist, a nucleic acid or an antigen.
5. The method of claim 4, wherein said pro-apoptosis agent is selected from the group consisting of gramicidin, magainin, melittin, defensin, cecropin, (KLAKLAK)₂ (SEQ ID NO:1), (KLAKKLA)₂ (SEQ ID NO:2), (KAAKKAA)₂ (SEQ ID NO:3) and (KLGKKLK)₃ (SEQ ID NO:4).
6. The method of claim 5, wherein the pro-apoptosis agent is (KLAKLAK)₂ (SEQ ID NO:1).
7. The method of claim 4, wherein the anti-angiogenic agent is selected from the group consisting of thrombospondin, angiostatin, pigment epithelium-derived factor, angiotensin, laminin peptides, fibronectin peptides, plasminogen activator inhibitors, tissue metalloproteinase inhibitors, interferons, interleukin 12, platelet factor 4, IP-10, Gro-β, thrombospondin, 2-methoxyoestradiol, proliferin-related protein, carboxiamidotriazole, CM101, Marimastat, pentosan polysulphate,

angiopoietin 2 (Regeneron), interferon-alpha, herbimycin A, PNU145156E, 16K prolactin fragment, Linomide, thalidomide, pentoxifylline, genistein, TNP-470, endostatin, paclitaxel, Docetaxel, polyamines, a proteasome inhibitor, a kinase inhibitor, a signaling peptide, accutin, cidofovir, vincristine, bleomycin, AGM-1470, platelet factor 4 and minocycline.

8. An isolated peptide of 100 amino acids or less in size, comprising at least 3 contiguous amino acids of a sequence selected from the group consisting of SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:13, SEQ ID NO:14, SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21, SEQ ID NO:22 and SEQ ID NO:144.
9. The isolated peptide of claim 8, wherein said peptide is 50 amino acids or less in size.
10. The isolated peptide of claim 8, wherein said peptide is 25 amino acids or less in size.
11. The isolated peptide of claim 8, wherein said peptide is 10 amino acids or less in size.
12. The isolated peptide of claim 8, wherein said peptide is 7 amino acids or less in size.
13. The isolated peptide of claim 8, wherein said peptide is 5 amino acids or less in size.
14. The isolated peptide of claim 8, wherein said peptide comprises at least 5 contiguous amino acids of a sequence selected from the group consisting of SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:13, SEQ ID NO:14, SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21, SEQ ID NO:22 and SEQ ID NO:144.
15. The isolated peptide of claim 14, wherein said peptide is attached to a molecule.

16. The isolated peptide of claim 15, wherein said molecule is a drug, a chemotherapeutic agent, a radioisotope, a pro-apoptosis agent, an anti-angiogenic agent, a hormone, a cytokine, a growth factor, a cytotoxic agent, a peptide, a protein, an antibiotic, an antibody, a Fab fragment of an antibody, an imaging agent, survival factor, an anti-apoptotic agent, a hormone antagonist or an antigen.
17. The isolated peptide of claim 16, wherein said pro-apoptosis agent is selected from the group consisting of gramicidin, magainin, mellitin, defensin, cecropin, (KLAKLAK)₂ (SEQ ID NO:1), (KLAKKLA)₂ (SEQ ID NO:2), (KAAKKAA)₂ (SEQ ID NO:3) and (KLGKKLG)₃ (SEQ ID NO:4).
18. The isolated peptide of claim 16, wherein said anti-angiogenic agent is selected from the group consisting of thrombospondin, angiostatin, pigment epithelium-derived factor, angiotensin, laminin peptides, fibronectin peptides, plasminogen activator inhibitors, tissue metalloproteinase inhibitors, interferons, interleukin 12, platelet factor 4, IP-10, Gro-β, thrombospondin, 2-methoxyestradiol, proliferin-related protein, carboxamidotriazole, CMI01, Marimastat, pentosan polysulphate, angiopoietin 2 (Regeneron), interferon-α, herbimycin A, PNU145156E, 16K prolactin fragment, Linomide, thalidomide, pentoxifylline, genistein, TNP-470, endostatin, paclitaxel, Docetaxel, polyamines, a proteasome inhibitor, a kinase inhibitor, a signaling peptide, accutin, cidofovir, vincristine, bleomycin, AGM-1470, platelet factor 4 and minocycline.
19. The isolated peptide of claim 16, wherein said cytokine is selected from the group consisting of interleukin 1 (IL-1), IL-2, IL-5, IL-10, IL-11, IL-12, IL-18, interferon-γ (IF-γ), IF-α, IF-β, tumor necrosis factor-α (TNF-α), or GM-CSF (granulocyte macrophage colony stimulating factor).
20. The isolated peptide of claim 8, wherein said peptide is attached to a macromolecular complex.
21. The isolated peptide of claim 20, wherein said complex is a virus, a bacteriophage, a bacterium, a liposome, a microparticle, a magnetic bead, a yeast cell, a mammalian cell or a cell.

22. The isolated peptide of claim 20, wherein said peptide is attached to a eukaryotic expression vector.
23. The isolated peptide of claim 22, wherein said vector is a gene therapy vector.
24. The isolated peptide of claim 14, wherein said peptide is attached to a solid support.
25. A method of targeting delivery to an organ or tissue, comprising:
 - a) obtaining a peptide according to claim 14;
 - b) attaching the peptide to an agent; and
 - b) administering the peptide and agent to a subject.
26. The method of claim 25, wherein the subject is a human, a mouse, a dog, a cat, a rat, a sheep, a horse, a cow, a goat or a pig.
27. The method of claim 25, wherein the agent is a drug, a chemotherapeutic agent, a radioisotope, a pro-apoptosis agent, an anti-angiogenic agent, an enzyme, a hormone, a cytokine, a growth factor, a cytotoxic agent, a peptide, a protein, an antibiotic, an antibody, a Fab fragment of an antibody, an imaging agent, an antigen, a survival factor, an anti-apoptotic agent, a hormone antagonist, a virus, a bacteriophage, a bacterium, a liposome, a microparticle, a magnetic bead, a microdevice, a yeast cell, a mammalian cell, a cell or an expression vector.
28. A method of targeted placental delivery comprising:
 - a) obtaining a peptide comprising at least three contiguous amino acids of a sequence selected from SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11 or SEQ ID NO:144; and
 - b) administering the peptide to a pregnant subject.
29. The method of claim 28, further comprising attaching an agent to the peptide.
30. The method of claim 29, wherein the agent is a therapeutic agent.
31. The method of claim 30, wherein the therapeutic agent induces labor in said subject.

32. The method of claim 30, wherein the therapeutic agent is selectively delivered to a fetus.
33. A method of screening compounds for teratogenic activity comprising:
- a) obtaining a receptor that binds to a placenta targeting peptide; and
 - b) screening compounds for their ability to bind to the receptor.
34. The method of claim 33, wherein the placenta targeting peptide is selected from the group consisting of SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11 or SEQ ID NO:144.
35. The method of claim 33, wherein the receptor comprises at least part of the sequence of FcRn/ β_2 M.
36. The method of claim 31, wherein the placenta targeting peptide comprises SEQ ID NO:5.
37. The method of claim 1, wherein the targeting peptide binds to a prohibitin receptor protein complex.
38. The method of claim 1, wherein the targeting peptide is part of an antibody or antibody fragment.
39. A method of treating a lipodystrophy comprising:
- a) obtaining a targeting peptide selective for adipose tissue;
 - b) attaching the peptide to a therapeutic agent to form a complex;
 - c) administering the complex to a subject; and
 - d) treating lipodystrophy.
40. The method of claim 39, wherein the targeting peptide comprises at least three contiguous amino acids of a sequence selected from SEQ ID NO:13, SEQ ID NO:14, SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:22.
41. The method of claim 39, wherein the targeting peptide has the amino acid sequence of SEQ ID NO:19 or SEQ ID NO:22

42. The method of claim 39, wherein the lipodystrophy is related to infection with human immunodeficiency virus (HIV).
43. The method of claim 42, wherein the lipodystrophy is induced by treatment with a retroviral protease inhibitor.
44. The method of claim 39, further comprising reducing blood lipid levels.
45. The method of claim 39, further comprising reducing abdominal fat.
